Mr. Holmes stated that he would not proceed with the fourth charge. Opening the case, he said that Dr. Macdonald, the complainant, had been for some years associated with a Russian medical man and biochemist, Dr. N. E. Ischlonsky, who had held certain high continental posts. Dr. Ischlonsky's work had been in recent years chiefly connected with the investigation of internal secretions. He had succeeded in making a preparation of embryonic tissue to which he had given the name "hormactan," and which had given good clinical results. Among the patients whom Dr. Ischlonsky had successfully treated with this preparation had been the wife and family of a Mr. Archibald Sharp; this gentleman had been so grateful and had formed such a high opinion of the value of the treatment that he had made repeated requests to be allowed to exploit it commercially; Dr. Ischlonsky had, however, refused to allow him to do so. In October, 1930, Mr. Sharp had asked Dr. Ischlonsky to grant an interview to Mr. Nesfield, who had asked him for a quantity of his preparation in order that he might treat two patients whom he had named. One of these was a man of some eminence in the State and in the City of London, who had been a member of the War Cabinet; Mr. Holmes disclosed his name in writing to the Council and requested that he might refer to this gentleman as "Mr. B." The Council granted this request. Dr. Ischlonsky had considered that he was safe in trusting a member of the medical profession with his preparation, and had therefore supplied the respondent with 15 ampoules for £120, stipulating that he should be given full clinical details of the treatment. The respondent had sent him details of a patient 6 ft. 2 in. in height, 16 st. in weight, and 52 years of age, of extremely powerful and muscular build. The blood pressure had been 135–140. As a result of the treatment the stature had increased by 1½ in. and the stance and sight had improved.

The complainant had in November, 1931, read a news article in the *Daily Express* referring in sensational terms to an article in the *Medical World* dated the same day, in which the respondent described the results of treatment by a preparation which he called vit alexin; the *Daily Express* article reproduced some of the clinical details, and among them was a case which corresponded exactly to the description of the patient whom Mr. Nesfield had informed Dr. Ischlonsky that he had treated with the hormactan supplied by the latter. Dr. Macdonald had secured the article in the *Medical World*, in which Case 1 was described as a case of general debility in a powerful man of 50 with a strong personality, who had been suffering from lassitude and decreased resistance to pneumococci, whose blood pressure had been 140 and his pulse-rate 60 and who could not read a newspaper without reading glasses. After 15 intramuscular injections of vit alexin at weekly intervals his skin had looked younger and his stature had increased by 1½ in. owing to his more erect stance and the increased tone of the intravertebral discs. Mr. Holmes pointed out that the wording of this case was practically the same as the wording of the clinical report Mr. Nesfield had sent to Dr. Ischlonsky. He pointed out that in both reports the words "the abdominal fullness disappearing" had occurred, and that in both the patient had been described as "finding himself reading a newspaper quite easily with distance glasses"; in both it had been said that "his mental quickness and perception had increased enormously."

Dr. Macdonald had then asked Dr. Ischlonsky if he might take the matter up; the latter had at first been unwilling to give his consent, thinking that to take any steps would be undignified, but he had later yielded to the complainant's persuasion. Complainant had examined the correspondence between Dr. Ischlonsky and Mr. Sharp, and found such striking resemblances in Mr. Sharp's letters to passages in the *Medical World* article that it was obvious that Mr. Sharp and Mr. Nesfield had been working together. Prosecuting his inquiries, he had come across an article in the French newspaper *Lu* which he had discovered was a literal translation of an article in the Hungarian paper *Az Est*; these articles described the wonderful properties of vit alexin and could only have emanated from the respondent.

Dealing with the charges in detail, he submitted that Mr. Sharp's letters could only have been written with the collaboration of the respondent and provided ample evidence that he was associated with Mr. Sharp in the campaign for attracting patients by advertisement. On the second charge, he said that this article had contained an account of two cases which had not appeared in the English articles and which, therefore, had presumably been supplied by the respondent. On the third charge, he pointed out that the mere fact that Mr. Nesfield had an agreement with the Vit Alexin Laboratories—Mr. Sharp's firm—to manufacture his preparation showed that he could not have disclosed it to the profession. On the fifth charge the same evidence was good, but Mr. Holmes withdrew the suggestion that respondent had enclosed a copy of the circular mentioned in charge 1 (*b*). Charge 6, which he had already dealt with, he submitted was the most serious of all.

Dr. William G. Macdonald testified to his statutory declaration. Cross-examined by Lord Erleigh, he said that a commercial man who tried to induce a doctor to enter into such an arrangement as Mr. Sharp had proposed to Dr. Ischlonsky would not meet with his approval. He was not suggesting that Mr. Nesfield had stolen Dr. Ischlonsky's invention, nor that Mr. Nesfield's preparation was in the nature of a quack remedy; he had no knowledge of it. His motive in complaining was to redress a slur on the profession. He admitted that the lay press often reproduced medical articles without the knowledge or consent of the author, but as the *Medical World* was published on Friday, the *Daily Express* could not have copied the article on the same day without prearrangement. He considered it significant that, whereas in the *Medical World* the age in the case of general debility was given as 50, in the *Daily Express* the age was given as 52. This patient had been described in one of Mr. Sharp's and would abstain from drink in the future. All the offences had been committed outside his district and none had been connected with any patient; no insured patient had ever complained. The conclusion of the inquiry—in view of all these facts—had been that the respondent would probably not offend again, and he had been put on probation for a year by the Minister. Mr. Gover had appeared before the Council in 1921, had been put on probation for a year, and had renewed his solemn promise to abstain from alcohol. From that day to this the Council had had no further information of any misdemeanour. In February last he had been found careering down the footway of a narrow road in the City, scattering pedestrians in all directions.

Sergeant Frank Watts, of the Metropolitan Police, testified to his arrest of Mr. Gover. He had found a large crowd, and a car moving on the footway. He had concluded that the driver was under the influence of drink, and had asked him to leave the car. The respondent had pleaded guilty through his counsel at the hearing on March 2nd. A charge of dangerous driving had been dismissed.

Cross-examined by Mr. Frampton, he said the doctor had been "a perfect gentleman" throughout and that there was only just room for two vehicles to pass in that thoroughfare; a careful driver might mount the pavement to pass another car. Re-examined, he said he had never seen a driver mount the pavement in that road before.

Mr. Frampton, addressing the Council, expressed respondent's profound regret that he had broken his undertaking. He asked if there were any statute of limitation for past offences and whether the punishment already received was not enough. He read a report from the police in 1922 giving Mr. Gover a very high character professionally. The doctor had taken a little alcohol, as he found it gave him great relief from colitis. He had been arrested immediately on leaving a club, just as he had started the car.

Mr. Frampton then called a number of medical and lay witnesses to Mr. Gover's character. They spoke enthusiastically of his work among the poor and of his reputation, and denied personal knowledge of any alcoholic habits.

After deliberation in camera the President announced that Mr. Gover would be called upon to appear again before the Council in May, 1933. The Council had found the charge proved, but hoped that Mr. Gover would abstain strictly from alcohol in future, and they had therefore postponed judgment.

A QUESTION OF CERTIFICATES.

The Case of Thomas Turnbull Tiplady, registered as of 102, Rye-hill, Newcastle-upon-Tyne, L.M.S.S.A. Lond. 1919, who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner (1) You did on three separate occasions—namely, on Nov. 22nd, 1919, June 7th, 1930, and July 8th, 1930, furnish certificates to the Ministry of Pensions relative to a claim by an ex-soldier John Ewart to a war pension (of which the second was on the official form M.P.A.O. 38) which were misleading and improper in that you gave a misleading and unreliable history of the post-war health of the said John Ewart from June, 1919, to the end of 1927; and (2) that on being questioned by the Ministry you alleged first that the certificates were based on your records, secondly that you had no record of the case, and thirdly that you had based them on Ewart's card which you had returned to the Insurance Committee, although no trace of the records can be found and the said Ewart had ceased to be insured in June, 1922. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Ministry of Pensions, the complainants, were represented by Mr. Glover, and Dr. Tiplady by Mr. Davis, of Messrs. Bulcraig and Davis.

Mr. Glover explained the position of the Minister of Pensions and the difficulty of his task, which involved great reliance on the certificates of private practitioners. He handed in the documents. In October, 1929, Ewart had made an application in respect of pulmonary tuberculosis. During the course of an examination by a Ministry of Pensions officer he had said he had suffered from blood-spitting in previous years. Later he had furnished certificates from Dr. Tiplady stating that the respondent had attended Ewart in 1927 for bronchitis. After inquiry about the blood-spitting, Ewart had furnished a further certificate stating that he had in fact had hæmoptysis at this period. The Ministry had then asked for further details and respondent had replied that he had no records. As his previous certificate had been given "as from records," the Ministry had written again. Dr. Tiplady had replied that the certificate had been made from the panel records, but inquiry of the Ministry of Health had shown that Ewart had not been an insured person since 1922, and that no records existed.

In reply to Dr. Bone, Mr. Glover said that the first part of the first charge—viz., the certificate dated Nov. 22nd, 1919—was now withdrawn.

Mr. Davis called Dr. Tiplady, who testified that Ewart had been under his care for some years and had suffered from bronchitis. In 1919 and 1920 Ewart had worked, casually, for him, and thereafter had consulted him professionally. He had been seeing him every second or third day up to the end of 1927. He had not mentioned blood-spitting in the first certificate because he had had the sputum tested and no tubercle bacilli had been found. His June and July certificates were accurate to the best of his knowledge and ability. When he had written his earlier certificate he had had a record; at that time he had been working with his father, but on his father's death a number of records had been accidentally destroyed by a secretary; it was therefore true that when he wrote to the Ministry on the material date he had had no record. The third communication, saying that he had sent the record to the Insurance Committee, was a mistake, due to confusion of two patients with the same name.

Mr. Davis then addressed the Council, giving Dr. Tiplady's assurance that he had never intended to do anything misleading. The Council found that the charges were not proved to their satisfaction.

A CHARGE OF ADVERTISEMENT.

The Case of Vincent Blumhardt Nesfield, registered as of Sandhurst, Kent, M.R.C.S. Eng. 1901, L.R.C.P. Lond. 1901, who had been summoned to appear before the Council on the following charge:—

"That, being a registered medical practitioner, you have sought to attract to yourself patients or to promote your own professional advantage by means of all or any of the following acts: (1) By being associated with or employed by an individual and/or firm who to your knowledge sought to attract patients by advertising and canvassing through the medium of—(*a*) an article in the *Daily Express* of Nov. 6th, 1931, and (*b*) an undated commercial circular, both relating to an alleged remedy for diabetes, pneumonia, blood poisoning, high blood pressure, epilepsy, mental incapacity, neurasthenia, general debility and other human ailments, known as vit alexin. (2) By advertising and canvassing through the medium of an interview given to and/or an article published in the newspaper *Az Est* of Buda-Pest and/or the newspaper *Lu* of Paris (Jan. 29th, 1932) relating to the said alleged remedy. (3) By keeping secret from the medical profession and from the public the formula or process for the production of the said alleged remedy, and being interested in its commercialisation as a secret remedy. (4) By publishing in the *Medical World* of the said Nov. 6th, was not the one described to Dr. Ischlonsky. If he had known Sharp was organising this campaign, he would have stopped it.

Cross-examined, he said he had mentioned no names to Dr. Ischlonsky. Mr. Sharp had been Dr. Ischlonsky's business agent, and respondent had obtained the ampoules through him. The price was £150, but he had obtained a rebate of £30, which Dr. Ischlonsky offered for every patient he introduced.

He affirmed that he had told Dr. Ischlonsky frankly that he had been interested in hormones. He had considered obtaining a second series of ampoules. He thought the description of "tout" rather strong for Mr. Sharp; he was familiar with travellers from drug firms. Asked whether he condemned Mr. Sharp's conduct in acting as agent for Dr. Ischlonsky, he said that he could not criticise a foreign doctor; it was "all a matter of regulations." He had had no conversation with Mr. Sharp about the handling by the latter of the commercial rights of vit alexin until some time in the summer of 1931. Mr. Sharp had then asked whether he could "run" the preparation for respondent, who had replied that he was not very anxious for anybody to run it, because he had only been making enough for himself. At a subsequent interview, however, in the autumn, he had said that he supposed that somebody would have to do it as he could not. Mr. Sharp was to run the preparation and "do what was right" by the respondent, who had informed him that he was not the principal. He had not made any arrangement before the date of Sharp's letter to Dr. Kousnetzoff, and knew nothing about the letter. Mr. Sharp had known that respondent was writing an article for a medical journal; the respondent had shown it to him at his residence at Sandhurst in the summer. Mr. Sharp had read a little of it, but without comprehension, and had not been given a copy. He had seen it again in respondent's room in London and had thought it "rather a poor article."

In answer to the Legal Assessor, respondent said that Mr. Sharp might have had the article for an appreciable time, for respondent's brother, who had been in close connexion with Mr. Sharp, had had it in his possession. He had not made any inquiry about Mr. Sharp's prospective methods. Questioned on the reference to the "elixir of life," which had appeared both in his article and in one of Mr. Sharp's letters, he said that Mr. Sharp might have seen the phrase in his article. He agreed that the writer of the letter must have copied matter from the article. It was not, however, true that he and Mr. Sharp had worked throughout in coöperation. He had not known that Mr. Sharp was writing to Dr. Kousnetzoff and others the letters he had written, or he would have had no further communication with him. The method was thoroughly "awful." Respondent was very bad at business; he had left it to Mr. Sharp, stipulating that he should be shown letters. He described as "not nice" Mr. Sharp's remarks about press propaganda and such matters. He had asked Mr. Sharp why he had used the name "Hormogen Laboratories," and had accepted the explanation that it was a business method. The name of the preparation had been changed from hormogen to vit alexin at about that time, and Mr. Sharp had also altered the letterhead. He accepted Mr. Sharp's use of Miss Saunders's name on the explanation that two names were needed on a piece of paper. He did not know when the partnership had started. She was receiving 5s. a week from it, and had refused to take more. Mr. Sharp was, respondent supposed, to take the whole of the rest of the profits. He had chosen Mr. Sharp because the latter had approached him first. Respondent had insisted on being in charge of the manufacture until the company was formed. He had taught Miss Saunders, and when the preparation was manufactured she had sent it to Mr. Sharp. He had charged Mr. Sharp nothing for it; Mr. Sharp had paid for the raw material and the 50 or 60 people employed in collecting it all over the country; it cost £100 to £200 a week, and could only be obtained at certain times of the year. Altogether Mr. Sharp had paid about £2000 for it. This would have made about 5000 1 c.cm. ampoules. In answer to the Legal Assessor, he said that the weekly output had been about 48 ampoules. Miss Saunders and "Mr. B." were the only people who knew the formula. Half the profits went to the firm, and the expenses were found by Mr. Sharp. In answer to Mr. Holmes, he said that he was glad to say that Miss Saunders had had no chemical training, but that the manufacture was not complicated, though absolute attention had to be paid to certain details, as in a Wassermann test and staining a slide. Explaining his description of the process as too "complicated, delicate, and intricate" for publication, in answer to the charge of concealment, and its divergence from his present answer, he said that he had been referring to the actual technique of preparation, which deserved that description.

Questioned about the company's assets, he said that the company, in January this year, had become the owner of a very expensive laboratory; this, he said, ought to have been mentioned in the agreement of sale. It had been paid for by Mr. Sharp, who should in time have charged it to the company. Mr. Sharp was a very wealthy man. He had purchased a suitable unoccupied house in Battle and turned it into a laboratory at the cost of about £1000. The house, of bungalow type, had cost £900, and the conversion £200 or more.

It would be very wrong, respondent said, for him to publish the details of the process now that Mr. Sharp had spent all this money. He did not remember how the article had been sent to the *Medical World*. He had sent it first to the *Practitioner* and then to the *Clinical Journal*; it had come back, and he must have then sent it to the *Medical World*. He had written asking them if they would like to publish it, and they had replied that they would. He had not known when it was to be published until he had seen it in the journal. He did not know how Mr. Sharp had known about it on Oct. 8th or 13th, when he had predicted to Mr. Douglas Walker and Dr. Kousnetzoff that it would be published on Nov. 6th, after the General Election, simultaneously with the article in the *Daily Express*. He thought that Mr. Sharp had made a pure guess, and suggested that the *Daily Express* had seen his article in the *Medical World* the day before its publishing date.

The discrepancy of age must, he said, have been an ordinary inaccuracy. He could not remember the right age; he had no case records. He had some "rather feeble" records, in tiny notebooks, of the patients he had treated with hormactan and hormogen; he kept them entirely in his head. The details of cases in the *Medical World* had been written entirely from memory. When his material had got bigger—over about 40 cases—he had started keeping notes, but the early patients were all persons intimately known to him. They lived in the same small village, and he had seen them daily for years, and knew every detail of them. He kept notes of consultations.

letters to Dr. Ischlonsky as a man of 50, but Mr. Nesfield had given the correct age in a letter as 52. Mr. Nesfield, therefore, must be the source of the information in the *Daily Express*.

Lord Erleigh: You have been busy!—I have examined this with care.

Asked what evidence he had of Mr. Nesfield's connexion with the advertising campaign, the complainant replied that he knew of it only by inference, saying that, after all, the whole of diagnosis was inference. It was plain from Mr. Sharp's letters and his association with Mr. Nesfield that if there had been no collaboration there would have been no publicity. The continental article referred to a case observed in "a large public assistance hospital," a class of hospitals which only existed in Britain, and of which no Hungarian reporter could have known by himself; only a medical man familiar with institutions in this country could have given this information. The complainant had ascertained from a Hungarian representative of the paper *Az Est* in London that the French article was a true translation of the Hungarian. Lord Erleigh put to the witness an article from a German paper concerning vit alexin, in which the phrase occurred "one of the best-known London hospitals confirm." The witness suggested that probably the same man had written both, although the "public assistance hospital" had not been mentioned. He did not know that this article had come from a Berlin paper, and therefore must, as Lord Erleigh put it, have "gone the rounds." The witness said that he himself did not profit by the success of hormactan, and did not regard vit alexin as a rival. The "Vit Alexin Laboratories," the address at 27, Walbrook, consisted of two rooms only, in which no manufacture could be carried on. The interest of Mr. Nesfield in the commercialisation of vit alexin was, he said, another matter of inference from the fact that Mr. Sharp, in letters to an assistant of Dr. Ischlonsky's called Dr. A. Kousnetzoff, had referred to his association with Mr. Nesfield and had made an offer of shares in the concern. Vit alexin was sold by chemists to the medical profession. He had written to "Mr. B." and had obtained an interview with him in order to ascertain whether he was the man referred to.

Re-examined, he stated that he had made notes of that conversation. (Mr. Holmes read the note, which was handed in.) "Mr. B." had stated that Case 1 in the *Medical World* article did not correspond to his case, and had suggested that an interview would smooth things over.

In reply to a question by Dr. J. Lorrain Smith, witness stated that the French article contained the phrase "hôpital d'assistance publique."

Dr. N. E. Ischlonsky, examined, corroborated Dr. Macdonald's evidence. This closed the case for the complainant.

Defence.

Lord Erleigh then called "Mr. B.," who testified that he had known respondent for about seven and a half years. He was himself very much interested in scientific research; he held the degree of M.D. Edin., and had early in his life been interested in the ductless glands; 25 years ago he had been awarded a gold medal for a thesis on the subject. He had worked in this field with respondent, who had done most of the experiments on vit alexin with his knowledge and frequently at his expense. He had supplied the money and also the body on which to experiment! Respondent had a practice near his residence and a small cottage hospital, and did much practice without remuneration. A friend had informed witness of hormactan, and he had asked respondent to obtain some for him. He had paid £120 for 15 ampoules; it had been wanted for experiment, not for treatment. He gave details of the results of the experiments, which had taken different forms. He had supplied all the material for Mr. Nesfield's letter to Dr. Ischlonsky; the details represented accurately the results which had occurred in himself. At the interview with Dr. Macdonald he had stated definitely that the *Medical World* Case 1 did not refer to himself; he testified that he knew the name of the man to whom it did refer, and wrote it down for the information of the Council. The man was a personal friend, and would have come forward if he had not had to leave for South Africa just before the hearing.

Lord Erleigh then called Mr. Nesfield, who gave details of his career. He had obtained the Fellowship of the Royal College of Surgeons at the age of 23 and had invented the chlorine sterilisation of drinking water. His standard text-book on plague was still used in all medical schools in India. He ran a cottage hospital at his own expense, and his income, including his pension, amounted to about £900. He had been interested in the ductless glands for 18 years. He had collaborated with "Mr. B." for about seven years, and they had worked independently and compared notes. He had first treated patients with a preparation kindred to vit alexin about the end of 1928. He had first heard of hormactan from "Mr. B." in the autumn of 1930, when that gentleman had sent him a circular describing it; on the same day Mr. Sharp had called on him for the first time and told him of it, and also his own brother had asked him by telephone if he had heard of it. His brother was a friend of Mr. Sharp. He had administered two doses to "Mr. B." but then had fallen ill. In 1931 he had started manufacturing vit alexin, which he had previously called hormogen, in his laboratory in Sandhurst, instructing Miss Saunders, his wife's companion, in its preparation. She had had two girls under her. He had ceased to play an active part in September, 1931. The laboratory was now in Battle, Sussex. The company had been formed in February, 1932, half the shares being held by Miss Saunders as a trustee for respondent's wife and four children. There was no prospect of profit, and he was £250 out of pocket. He was not a shareholder. The article in the *Medical World* fairly represented the position. He had given no information towards the article in the *Daily Express*. A representative of the paper had called on him with the *Medical World* article, and he had said: "You mustn't put that in; if you do, I shall get into a terrible row." The representative had, however, declined to refrain from publishing it. A newspaper could get the *Medical World* the day before the public could. He had not drawn up the offending circular. Mr. Sharp had written it entirely from material in the article and respondent had never seen it. He had remonstrated furiously with Mr. Sharp, who had broken faith with him in printing anything without his knowledge, and the circular had at once been recalled. Questions in letters from doctors had been answered and the value of vit alexin to the particular patient discussed; lay persons writing had all been referred to their doctors. He knew nothing about the continental articles. He held that he would have been wrong to disclose the formula; if he had, England would have been swamped with foreign preparations of the kind. He believed in it as a wonderful remedy. The case in the *Medical World* patient's head to disengage the pole from the sling, had turned away in watching the direction of the pole which he was removing; simultaneously the attention of the probationer nurse, who was at the patient's feet, happened to be momentarily distracted, while the anæsthetist had turned his back to pick up certain apparatus. The jury, in returning a verdict of the cause of death as already stated, added a recommendation that an additional nurse or attendant should be at the side of the patient in future.

Snail in Gingerbeer Bottle.

The medical profession is not so directly interested as the legal in the important House of Lords decision on May 26th about the snail in the gingerbeer bottle. A shop assistant, claiming £500 damages in a Scottish court, alleged that she had contracted a serious illness as the result of drinking part of the contents of a gingerbeer bottle which was afterwards found to contain a dead snail. No witnesses described the nature or origin of the illness; the judges were concerned with the mere preliminary point whether the allegations would support a course of action. Both parties agreed that the Scots law and the English law were here the same. The legal difficulty appears from a study of the earlier decisions. In Longmeid *v.* Holliday (1851) a shopkeeper sold a defective lamp with a bona fide warranty of soundness. The lamp exploded and injured somebody who was not privy to the contract of sale, but whose use of the lamp had been contemplated by the shopkeeper in selling it. The injured person was held to have no cause of action; he could not sue on the contract because he was not a party to it, and he could not sue apart from the contract because there was no fraud in the warranty. In Le Lievre *v.* Gould (1893), where a surveyor had given building certificates negligently but without fraud, and mortgagees had advanced money on the faith of the certificates, Lord Esher asked what duty there could be (where there was no fraud) when there was no contractual relationship between the parties. "A man is entitled to be as negligent as he pleases towards the whole world if he owes no duty to them." On the other hand, in George *v.* Skivington (1869), where a chemist sold a bottle of poisonous hair-wash to a customer, knowing it was for the customer's wife's use, and where she was thereby injured, the chemist was made to pay damages. In the recent case in the House of Lords, Lord Buckmaster said that George *v.* Skivington was bad law and ought to be buried in oblivion. Lord Atkin, however, delivering a judgment in which the majority of the House concurred, differed from Lord Buckmaster and invited their lordships to make the law conform to common sense. Here, he said, is a manufacturer who sells his product in such a form as to show that he intends it to reach the ultimate consumers in the form in which it left him, with no reasonable opportunity of intermediate examination (the gingerbeer bottle was of opaque glass and its contents could not be inspected till they were poured out); if the manufacturer knows that the absence of reasonable care in the preparation or putting up of the product is likely to cause injury to the health of the consumer, then he owes a duty to take that reasonable care. No more important problem, thought Lord Atkin, had occupied the judicial attention of the House of Lords—important in its public health aspect as well as in legal significance. If the poisoned consumer had no right to sue the negligent manufacturer, it would be a grave defect in our law.

NATIONAL INSTITUTE FOR THE DEAF.

THE eighth annual meeting of this institute was held at the Egyptian Hall of the London Mansion House on May 27th, when the Lord Mayor, Sir Maurice Jenks, presided, and in welcoming the supporters of the institute, emphasised the need for educating the deaf and the valuable work of the institute in this direction.

Mr. A. J. STORY, secretary of the Institute, then summarised the report of the executive committee for the past year, which showed that the six associations in affiliation with the National Institute, and covering England and Scotland, had continued their work of uniting public and voluntary effort. The report stressed the need for voluntary workers and the inadequacy of revenue and office accommodation. Other matters noticed in the report were the founding of a hostel for working deaf boys, and the improvement effected at Richardson House, the home for deaf women. The committee had to regret the recrudescence during the year of exploitation of the deaf by travelling "specialists" and others professing to cure head noises and deafness. The work of the medical committee had been found valuable, while the fact emerged that at least £40,000 was needed to promote the higher education of the deaf.

Mr. JOHN TENNANT, the hon. treasurer, said that in spite of every possible care the income for 1931–32 had failed to meet the expenditure by £110. There were less than 200 annual subscribers, and the aggregate subscription was only £318. The donations, mostly in response to special appeals, amounted to only £1259, but had it not been for these the deficit would have been indeed large. He felt sure that more than 200 people out of the forty millions in this country would subscribe if they knew of the present needs of the Institute.

Lord CHARNWOOD, the President, in moving the adoption of the report and accounts (both of which had already been circulated), after referring to the disabilities under which the deaf lived and to the skill that was required in relieving their plight, said that in response to pressure for several years on successive Ministries they had now succeeded in procuring an inquiry on the part of the Government, conducted by a capable investigator, into the efficiency of teaching in schools provided for the deaf and in the after-effects on their future lives. That inquiry by Dr. Eichholz had just been completed, and he was confident that the Government would make its conclusions public quite soon, when he hoped that the needed work would begin. It would be the business of the National Institute for the Deaf to press the Government to take with the least possible delay the steps forward which were pointed out in this report. Mr. Baldwin and Mr. Greenwood, continued Lord Charnwood, were the first important Ministers who had declared that the condition of the deaf needed such an inquiry as that to which he had referred. The activities of the work now covered England and Scotland, though not yet Wales, and were supported by local authorities and missions. Another matter was the admirable work done by the medical committee, which, if funds could be obtained, would be able to put the provision of aid for those who were becoming deaf on the same scientific basis as was already done for those with defective sight by the aid of glasses. Also there was now before the public a perfectly sound scheme, threshed out by educational experts, for a school for

Mr. Archibald James Menzies Sharp, examined, admitted the authorship of the letters before the court. Mr. Nesfield, he said, had known nothing about the letters or witness's proposed action. Cross-examined, he said that he hoped he was still a friend of Dr. Ischlonsky. He had not sent a circular recommending people to go to Dr. Nesfield for treatment, but had written to various people—leaders of finance and industry—recommending them to go to Dr. Ischlonsky, partly out of gratitude to the latter and partly from a sense of duty, as he felt that hormactan was a valuable discovery and would benefit their health in the present crisis, to the good of the country. He had introduced respondent to Dr. Ischlonsky, but the object of the interview had not been discussed in his presence. He knew that the respondent had obtained ampoules from Dr. Ischlonsky to treat a patient; he had inferred that they were for "Mr. B." At the beginning of 1931 he had begun to meet respondent and had discussed his work on hormones with him. In June he had hoped to be allowed to put the preparation before the medical profession. Respondent had all along refused to have anything to do with the commercialisation of the substance, and had given witness the benefit of his work on it at some time in the middle of the year. There had been no written agreement. He had made the arrangement before writing to Dr. Kousnetzoff. He had insisted that, after the respondent's years of research, his attitude was unreasonable and that his children ought to benefit. Asked why he thought that respondent made this gift to him, he said, because respondent was in entire sympathy with his attitude to Dr. Ischlonsky. In answer to the Legal Assessor, he said that he had been anxious that the poor, as well as the rich, should have the blessings of this treatment. Respondent had emphatically objected to the first circular and witness had had to visit him. He had then withdrawn it from the chemists to whom it had been supplied. He had not arranged for the publication of the article in the *Daily Express*, nor did he know that it was to be published on the same day as the *Medical World* article; he had thought it would appear on the following day. Asked why, he answered that he had not known when the *Medical World* article would become available.

Brig.-General C. L. Porter, examined, stated that he had become acquainted with Mr. Nesfield in 1919 in India, at a time when there had been a bad epidemic of plague. The disappearance of this epidemic had been due to the skill and devotion of respondent, of which witness could not speak too highly. Respondent was an outstanding man in many other ways, and was now a personal friend of the witness.

After counsel had delivered their addresses, the Council deliberated in camera. When strangers were readmitted, the President announced that all the charges except the fourth had been proved to its satisfaction and that it directed the Registrar to erase from the Register the name of Vincent Blumhardt Nesfield.

This concluded the hearing of disciplinary cases. The cases of Adam Hamilton and Andrew St. Lawrence Burke, summoned together on a charge of canvassing, were adjourned until the winter session, Dr. David Holmes (the complainant) being unable to attend through illness.

The Council restored to the Dental Register the name of Joseph Jennings.

MEDICINE AND THE LAW.

Sale of Poisons in Chemist's Shop.

THE Pharmaceutical Society continues its battle for the proper enforcement of the law relating to the sale of poisons. Under Section 3 of the Poisons and Pharmacy Act, 1908, a duly registered pharmaceutical chemist commits an offence unless, in all the premises where he carries on business as a chemist, the business is "bona fide conducted by himself or some other duly registered pharmaceutical chemist or chemist or druggist." The Society brought an action under this Section against a Wendover chemist who, for 42 hours in the week, was engaged in work a mile away at Halton Camp. During the period of his absence he left an unqualified assistant in charge of the Wendover shop, who sold the public any goods that might be asked for. The assistant was proved to have sold lysol on three separate occasions. The county court judge at Aylesbury, before whom the proceedings for a penalty were taken, held that Section 3 had not in the circumstances been infringed. The learned judge felt himself bound by the decision in Watkinson's case last year. That was a case where sale of poisons had taken place by means of an automatic machine outside the chemist's shop; it was there held that, as a matter of fact, the automatic machine was part of the premises where the business was carried on, but Mr. Justice Talbot took the view that there had been no offence against Section 3, because no unqualified assistant had been employed in effecting the sale through the machine. On appeal from the Aylesbury County Court Sir Leslie Scott, on behalf of the Society, sought to distinguish the Wendover case from the automatic machine case; he argued that the word "conducted" connoted some more physical supervision of the business by the chemist himself than the words "carried on." The King's Bench Division dismissed the appeal, but gave leave for further appeal. There is indeed much to be said for the argument that the Pharmacy Acts were intended to give the public a genuine protection from the dangers of sale by unqualified persons, and therefore that the control by the duly qualified and registered chemist must be real and not merely nominal.

Unusual Accident in Hospital.

An unfortunate accident in a hospital operating theatre was investigated during an inquest at Northampton last month in a case where death was found to have been due to acute meningitis. A patient was about to be operated upon for mastoid abscess. The anæsthetic had been administered and the patient had been lifted from the trolley to the operating table, when somehow the body slipped from the table and fell to the floor. A post-mortem examination showed that the inflammation of the brain was so acute that there was no hope for the patient, fall or no fall; there was some evidence that the effects of the fall might in fact have been mitigated by the anæsthetic. A legal representative appearing at the inquest on behalf of the hospital authorities, who was permitted the by no means universal privilege of addressing the coroner's jury, urged that there was no evidence of negligence. The coroner, in summing up, said the fall should not have occurred. Apparently the porter, standing at the patient's head to disengage the pole from the sling, had turned away in watching the direction of the pole which he was removing; simultaneously the attention of the probationer nurse, who was at the patient's feet, happened to be momentarily distracted, while the anæsthetist had turned his back to pick up certain apparatus. The jury, in returning a verdict of the cause of death as already stated, added a recommendation that an additional nurse or attendant should be at the side of the patient in future.

Snail in Gingerbeer Bottle.

The medical profession is not so directly interested as the legal in the important House of Lords decision on May 26th about the snail in the gingerbeer bottle. A shop assistant, claiming £500 damages in a Scottish court, alleged that she had contracted a serious illness as the result of drinking part of the contents of a gingerbeer bottle which was afterwards found to contain a dead snail. No witnesses described the nature or origin of the illness; the judges were concerned with the mere preliminary point whether the allegations would support a course of action. Both parties agreed that the Scots law and the English law were here the same. The legal difficulty appears from a study of the earlier decisions. In Longmeid *v.* Holliday (1851) a shopkeeper sold a defective lamp with a bona fide warranty of soundness. The lamp exploded and injured somebody who was not privy to the contract of sale, but whose use of the lamp had been contemplated by the shopkeeper in selling it. The injured person was held to have no cause of action; he could not sue on the contract because he was not a party to it, and he could not sue apart from the contract because there was no fraud in the warranty. In Le Lievre *v.* Gould (1893), where a surveyor had given building certificates negligently but without fraud, and mortgagees had advanced money on the faith of the certificates, Lord Esher asked what duty there could be (where there was no fraud) when there was no contractual relationship between the parties. "A man is entitled to be as negligent as he pleases towards the whole world if he owes no duty to them." On the other hand, in George *v.* Skivington (1869), where a chemist sold a bottle of poisonous hair-wash to a customer, knowing it was for the customer's wife's use, and where she was thereby injured, the chemist was made to pay damages. In the recent case in the House of Lords, Lord Buckmaster said that George *v.* Skivington was bad law and ought to be buried in oblivion. Lord Atkin, however, delivering a judgment in which the majority of the House concurred, differed from Lord Buckmaster and invited their lordships to make the law conform to common sense. Here, he said, is a manufacturer who sells his product in such a form as to show that he intends it to reach the ultimate consumers in the form in which it left him, with no reasonable opportunity of intermediate examination (the gingerbeer bottle was of opaque glass and its contents could not be inspected till they were poured out); if the manufacturer knows that the absence of reasonable care in the preparation or putting up of the product is likely to cause injury to the health of the consumer, then he owes a duty to take that reasonable care. No more important problem, thought Lord Atkin, had occupied the judicial attention of the House of Lords—important in its public health aspect as well as in legal significance. If the poisoned consumer had no right to sue the negligent manufacturer, it would be a grave defect in our law.

NATIONAL INSTITUTE FOR THE DEAF.

THE eighth annual meeting of this institute was held at the Egyptian Hall of the London Mansion House on May 27th, when the Lord Mayor, Sir Maurice Jenks, presided, and in welcoming the supporters of the institute, emphasised the need for educating the deaf and the valuable work of the institute in this direction.

Mr. A. J. STORY, secretary of the Institute, then summarised the report of the executive committee for the past year, which showed that the six associations in affiliation with the National Institute, and covering England and Scotland, had continued their work of uniting public and voluntary effort. The report stressed the need for voluntary workers and the inadequacy of revenue and office accommodation. Other matters noticed in the report were the founding of a hostel for working deaf boys, and the improvement effected at Richardson House, the home for deaf women. The committee had to regret the recrudescence during the year of exploitation of the deaf by travelling "specialists" and others professing to cure head noises and deafness. The work of the medical committee had been found valuable, while the fact emerged that at least £40,000 was needed to promote the higher education of the deaf.

Mr. JOHN TENNANT, the hon. treasurer, said that in spite of every possible care the income for 1931–32 had failed to meet the expenditure by £110. There were less than 200 annual subscribers, and the aggregate subscription was only £318. The donations, mostly in response to special appeals, amounted to only £1259, but had it not been for these the deficit would have been indeed large. He felt sure that more than 200 people out of the forty millions in this country would subscribe if they knew of the present needs of the Institute.

Lord CHARNWOOD, the President, in moving the adoption of the report and accounts (both of which had already been circulated), after referring to the disabilities under which the deaf lived and to the skill that was required in relieving their plight, said that in response to pressure for several years on successive Ministries they had now succeeded in procuring an inquiry on the part of the Government, conducted by a capable investigator, into the efficiency of teaching in schools provided for the deaf and in the after-effects on their future lives. That inquiry by Dr. Eichholz had just been completed, and he was confident that the Government would make its conclusions public quite soon, when he hoped that the needed work would begin. It would be the business of the National Institute for the Deaf to press the Government to take with the least possible delay the steps forward which were pointed out in this report. Mr. Baldwin and Mr. Greenwood, continued Lord Charnwood, were the first important Ministers who had declared that the condition of the deaf needed such an inquiry as that to which he had referred. The activities of the work now covered England and Scotland, though not yet Wales, and were supported by local authorities and missions. Another matter was the admirable work done by the medical committee, which, if funds could be obtained, would be able to put the provision of aid for those who were becoming deaf on the same scientific basis as was already done for those with defective sight by the aid of glasses. Also there was now before the public a perfectly sound scheme, threshed out by educational experts, for a school for

Mr. Archibald James Menzies Sharp, examined, admitted the authorship of the letters before the court. Mr. Nesfield, he said, had known nothing about the letters or witness's proposed action. Cross-examined, he said that he hoped he was still a friend of Dr. Ischlonsky. He had not sent a circular recommending people to go to Dr. Nesfield for treatment, but had written to various people—leaders of finance and industry—recommending them to go to Dr. Ischlonsky, partly out of gratitude to the latter and partly from a sense of duty, as he felt that hormactan was a valuable discovery and would benefit their health in the present crisis, to the good of the country. He had introduced respondent to Dr. Ischlonsky, but the object of the interview had not been discussed in his presence. He knew that the respondent had obtained ampoules from Dr. Ischlonsky to treat a patient; he had inferred that they were for "Mr. B." At the beginning of 1931 he had begun to meet respondent and had discussed his work on hormones with him. In June he had hoped to be allowed to put the preparation before the medical profession. Respondent had all along refused to have anything to do with the commercialisation of the substance, and had given witness the benefit of his work on it at some time in the middle of the year. The coroner, in summing up, said the fall should not have occurred. Apparently the porter, standing at the

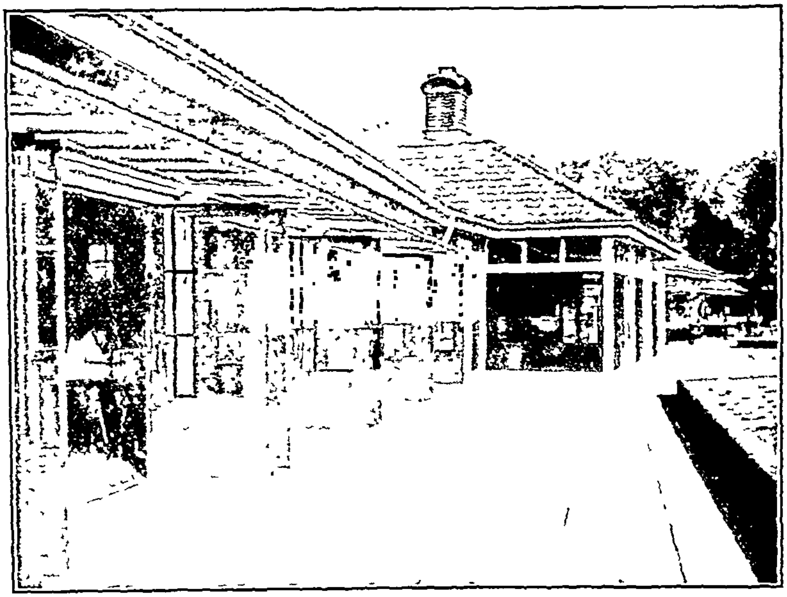
A CHILDREN'S HOSPITAL PAVILION.

NEW BUILDINGS AT TADWORTH COURT.

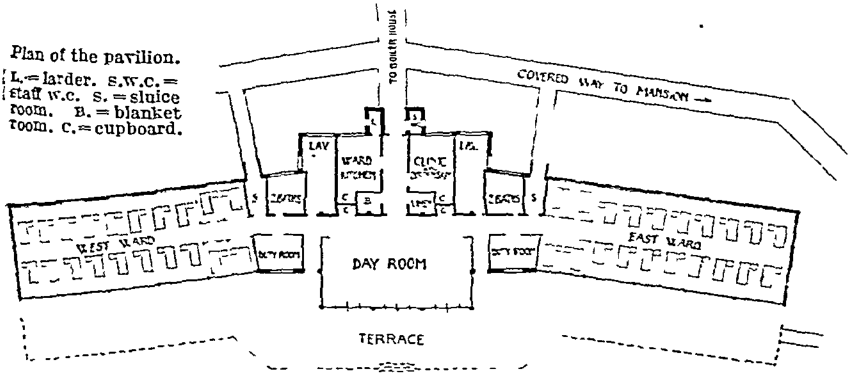


The new pavilion, from the terrace.

[Photograph by S. W. Newbery.

THE accompanying illustrations represent the first of 12 proposed open-air pavilions to be erected in connexion with the extension of the branch hospital at Tadworth Court of the Hospital for Sick Children, Great Ormond-street, London. It was opened by the Princess Royal last Monday.

The pavilions will be situated on vacant land of approximately 50 acres and will be spaced in the shape of a fan, with south aspect, and on the main axial road, which will give access by covered ways to all pavilions. The general lay-out provides for a central service kitchen, and near to the main road will be the power house, laundry, &c. The scheme also provides for a nurses' home and recreation room, chapel, pathological section, isolation ward, operating theatre, and electrical treatment ward.



Plan of the pavilion.

L.=larder. S.W.C.=staff W.C. S.=sluice room. B.=blanket room. C.=cupboard.

The first pavilion now erected is constructed with a steel frame and is fitted throughout with steel windows and steel folding doors, the latter being glazed with safety glass for the further protection of the children. Each pavilion accommodates 40 cots, and considerable space has been provided for gangways, thereby enabling all cots to be kept clear of the walls. Each pavilion is provided with a large lofty day room, approximately 40 ft. by 20 ft., and in either side are duty rooms which give uninterrupted supervision to the wards, the day room, and the external terraces. Immediately adjoining the duty rooms are the isolation cubicles, which are provided with removable partitions. Adequate lavatory accommodation is provided for each ward and there is a clinic and service kitchen, all of which are fitted with modern sanitary equipment and low pressure steam-heated sterilisers. The woodwork generally is faced with alder and fitted with special bright metal ironmongery which needs no cleaning.

Each pavilion is provided with broad terraces paved with stone, to enable cots to be wheeled out and to give a dry playing space for children who are able to get about.

The lighting of the wards is concealed in the ceiling and special pilot lights are provided for night use. The building is heated by low pressure steam, and a special feature is the concealed heat-ray panels in the ceilings and walls, the former giving an effect of comfort heat, and the latter direct heat at approximately floor level. By this means no floor space is lost, and there are no unsightly dust-collecting radiators. A secondary means of heating is provided by gas radiators in the event of an emergency.

The floor coverings of the wards and the day room are of Canadian maple, with an oak margin against the south front to allow for driving rains when the folding doors are open. Elsewhere floors are laid with marble terrazzo, laid in situ. Fire hydrants, fire-fighting appliances, and alarm bells, electric clocks and telephones, are all installed.

The architect for the scheme is Mr. H. Courtenay Constantine, F.R.I.B.A., of 82, Mortimer-street, London, W.

BIRMINGHAM ROYAL CRIPPLES' HOSPITAL.—Last year was the busiest yet experienced, but by careful supervision the expenditure was reduced by more than £2000. There are two hospitals with a total of 210 beds, a convalescent school with 74 beds, an out-patients' department, and a students' hospital, and during the year 1020 in-patients were treated, 217 of whom were tuberculous children. The average weekly cost was £2 11*s.* 8*d.*, and their stay 98·41 days, as against 106·02 in 1930. Out-patients numbered 4320 and the average cost of each was £4 4*s.* 8*d.* It is pointed out that one of the difficulties of a hospital of this character is that the local authorities have no power to make grants in respect of the orthopædic treatment of non-tuberculous adult patients, who formed 52 per cent. of those registered in 1931. The training committee emphasises the economic and vocational importance of larger centres.

the deaf which would give suitable boys and girls secondary education of a high quality. He believed that the work of the Institute was mainly hampered by the prevailing want of understanding on the part of the public of the needs of the deaf.

Mr. M. BIRLEY, the chairman of the executive committee, seconded the motion, which was unanimously adopted.

The Bishop of NORWICH said there were 40,000 deaf in the British Isles who ought to have all the help that could be given to them; 40,000 people who had never heard the sounds of the countryside, or the voices of those who loved them. Money was wanted to make these people useful members of the community, and he could not conceive of a better cause for public support. He moved "that this meeting, conscious of the grave disabilities arising from deafness in the lives of large numbers of citizens of this country, approves the efforts of the National Institute for the Deaf to ameliorate their conditions, and pledges itself to support the Institute and other bodies serving the interests of the deaf in every possible way."

This was seconded by the Rev. E. ST. G. SCHOMBERG, the Mayor of Westminster, and carried unanimously.

The meeting closed with votes of thanks to the retiring officers, who were re-elected.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE CHICAGO PUBLIC HEALTH INSTITUTE.

THE Public Health Institute of Chicago was founded over 12 years ago through the interest of certain prominent citizens who had become appalled by the amount of venereal disease in the city. The institute has always been of the no-profit type with high social ideals. It has provided treatment at low fees for people who could not pay the regular prices for antivenereal treatment. It has advertised widely to all the danger of venereal disease and the importance of early and adequate treatment. But in its early years it ran foul of the local medical profession. Objection was taken to some of the advertising and to the unfair competition of low prices and to the wholesale methods of treatment. A prominent Chicago physician was disciplined for his connexion with the institute. Feeling ran high, but the trustees kept their heads. Two years ago they invited seven members of the profession to form a medical advisory board. This board was invited to nominate the medical staff, to advise the trustees on questions of medical standards or policies, and to censor the advertisements. The efficiency of the institute has doubtless been increased and its place in the community assured. A very interesting and encouraging report for the year 1931 has just been issued. As an indication of the volume of work done, a total of 42,000 visits were made to the syphilis division in the main clinic alone. Only six patients required hospitalisation because of treatment reactions.

SEEKING A MALARIA RESERVOIR.

The federal public health service, in coöperation with the State Hospital at Columbia, South Carolina, has recently inaugurated a programme of study seeking to assure for the treatment of general paralysis a reliable reservoir of malaria parasites. Experiments are to be made with artificial culture media. An interest is also being taken in problems connected with the nurture and transportation of infected mosquitoes. There are, it would seem, some in this country who do not believe that malaria therapy is to be replaced by other methods of inducing pyrexia.

INSTITUTE OF MEDICAL PSYCHOLOGY.

THE main objects of this Institute were clearly defined, in order of importance, by Dr. H. B. BRACKENBURY, chairman of council, at the annual meeting which preceded luncheon at the Wharncliffe Rooms on May 31st. Treatment of individual patients came first, but only slightly less important was the self-imposed task of influencing public and medical opinion on the place which psychology should but does not yet take in the world of medicine. The training of workers, medical and lay, in the broad principles of psychotherapy was another important function of the clinic, and though at present funds were not yet available for serious and deliberate research, the correlation of mental and physical characteristics which was essentially research was part of the daily routine.

Mr. WALTER ROCH, the hon. treasurer, spoke of difficulties which had arisen quite recently, and would probably entail an additional capital expenditure of £700 before the Institute could move from its premises in Tavistock-square, of which the lease was expiring, to the more spacious quarters acquired in Torrington-square. Of the annual expenditure of £5000, about £2000 only came from patients' fees.

At the luncheon, which was well attended by friends of the Institute, Lady Erleigh spoke of the help given by members of the staff of the Institute when consulted by those concerned with the management of difficult children.

Sir HILTON YOUNG praised the wisdom of limiting the number of patients seen at the clinic; its fame must rest on the quality of the work done rather than on its quantity, though in fact well over 10,000 consultations had been held during the past year. More than 5000 cases had been treated in the 12 years of the Institute's existence, and recently 325 cases had been carefully followed up. The development of the Institute coincided with other new developments which the Mental Treatment Act, 1930, had made possible. Sir Hilton suggested the probability that the out-patient departments of mental hospitals would be concerned chiefly with the psychoses, and those of general hospitals with mental symptoms associated with physical disease, while the neurotics and psychoneurotics would be likely to gravitate to places such as the Institute of Medical Psychology, where prolonged treatment could be undertaken if required. Naturally there would be considerable overlapping in the type of patients seen. Neuroses and psychoneuroses were the characteristic physical evils of our times, and the Institute was doing a great work.

Dr. H. CRICHTON-MILLER, the hon. director, pointed out the urgent need of more floor space. There was no lack of men and women eager to become clinical assistants and to take a share in the work, but they could not be accommodated. The waiting-list of patients anxious to be treated had had to be closed before the last annual meeting and had not yet been reopened. New patients could of course be seen in consultation, but not for daily continuous treatment. Dr. Crichton-Miller said that the Institute was still battling against conservatism and obstruction within the medical profession, but the ideals and practical aims for which it stood were rapidly gaining ground.

A CHILDREN'S HOSPITAL PAVILION.

NEW BUILDINGS AT TADWORTH COURT.

THE accompanying illustrations represent the first of 12 proposed open-air pavilions to be erected in connexion with the extension of the branch hospital at Tadworth Court of the Hospital for Sick Children, Great Ormond-street, London. It was opened by the Princess Royal last Monday.

The pavilions will be situated on vacant land of approximately 50 acres and will be spaced in the shape of a fan, with south aspect, and on the main axial road, which will give access by covered ways to all pavilions. The general lay-out provides for a central service kitchen, and near to the main road will be the power house, laundry, &c. The scheme also provides for a nurses' home and recreation room, chapel, pathological section, isolation ward, operating theatre, and electrical treatment ward.

The first pavilion now erected is constructed with a steel frame and is fitted throughout with steel windows and steel folding doors, the latter being glazed with safety glass for the further protection of the children. Each pavilion accommodates 40 cots, and considerable space has been provided for gangways, thereby enabling all cots to be kept clear of the walls. Each pavilion is provided with a large lofty day room, approximately 40 ft. by 20 ft., and in either side are duty rooms which give uninterrupted supervision to the wards, the day room, and the external terraces. Immediately adjoining the duty rooms are the isolation cubicles, which are provided with removable partitions. THE CHICAGO PUBLIC HEALTH INSTITUTE.

THE Public Health Institute of Chicago was founded over 12 years ago through the interest of certain prominent citizens who had become appalled by the amount of venereal disease in the city. The institute has always been of the no-profit type with high social ideals. It has provided treatment at low fees for people who could not pay the regular prices for antivenereal treatment. It has advertised widely to all the danger of venereal disease and the importance of early and adequate treatment. But in its early years it ran foul of the local medical profession. Objection was taken to some of the advertising and to the unfair competition of low prices and to the wholesale methods of treatment. A prominent Chicago physician was disciplined for his connexion with the institute. Feeling ran high, but the trustees kept their heads. Two years ago they invited seven members of the profession to form a medical advisory board. This board was invited to nominate the medical staff, to advise the trustees on questions of medical standards or policies, and to censor the advertisements. The efficiency of the institute has doubtless been increased and its place in the community assured. A very interesting and encouraging report for the year 1931 has just been issued. As an indication of the volume of work done, a total of 42,000 visits were made to the syphilis division in the main clinic alone. Only six patients required hospitalisation because of treatment reactions.

SEEKING A MALARIA RESERVOIR.

The federal public health service, in coöperation with the State Hospital at Columbia, South Carolina, has recently inaugurated a programme of study seeking to assure for the treatment of general paralysis a reliable reservoir of malaria parasites. Experiments are to be made with artificial culture media. An interest is also being taken in problems connected with the nurture and transportation of infected mosquitoes. There are, it would seem, some in this country who do not believe that malaria therapy is to be replaced by other methods of inducing pyrexia.

INSTITUTE OF MEDICAL PSYCHOLOGY.

THE main objects of this Institute were clearly defined, in order of importance, by Dr. H. B. BRACKENBURY, chairman of council, at the annual meeting which preceded luncheon at the Wharncliffe Rooms on May 31st. Treatment of individual patients came first, but only slightly less important was the self-imposed task of influencing public and medical opinion on the place which psychology should but does not yet take in the world of medicine. The training of workers, medical and lay, in the broad principles of psychotherapy was another important function of the clinic, and though at present funds were not yet available for serious and deliberate research, the correlation of mental and physical characteristics which was essentially research was part of the daily routine.

Mr. WALTER ROCH, the hon. treasurer, spoke of difficulties which had arisen quite recently, and would probably entail an additional capital expenditure of £700 before the Institute could move from its premises in Tavistock-square, of which the lease was expiring, to the more spacious quarters acquired in Torrington-square. Of the annual expenditure of £5000, about £2000 only came from patients' fees.

At the luncheon, which was well attended by friends of the Institute, Lady Erleigh spoke of the help given by members of the staff of the Institute when consulted by those concerned with the management of difficult children.

Sir HILTON YOUNG praised the wisdom of limiting the number of patients seen at the clinic; its fame must rest on the quality of the work done rather than on its quantity, though in fact well over 10,000 consultations had been held during the past year. More than 5000 cases had been treated in the 12 years of the Institute's existence, and recently 325 cases had been carefully followed up. The development of the Institute coincided with other new developments which the Mental Treatment Act, 1930, had made possible. Sir Hilton suggested the probability that the out-patient departments of mental hospitals would be concerned chiefly with the psychoses, and those of general hospitals with mental symptoms associated with physical disease, while the neurotics and psychoneurotics would be likely to gravitate to places such as the Institute of Medical Psychology, where prolonged treatment could be undertaken if required. Naturally there would be considerable overlapping in the type of patients seen. Neuroses and psychoneuroses were the characteristic physical evils of our times, and the Institute was doing a great work.

Dr. H. CRICHTON-MILLER, the hon. director, pointed out the urgent need of more floor space. There was no lack of men and women eager to become clinical assistants and to take a share in the work, but they could not be accommodated. The waiting-list of patients anxious to be treated had had to be closed before the last annual meeting and had not yet been reopened. New patients could of course be seen in consultation, but not for daily continuous treatment. Dr. Crichton-Miller said that the Institute was still battling against conservatism and obstruction within the medical profession, but the ideals and practical aims for which it stood were rapidly gaining ground.

ing for differences in the standard of living, there is really no wide discrepancy in professional incomes in the two countries." Nor can they trace it to differences in the methods by which the doctors are remunerated. The really important matter is that in Germany the doctors are under lay control, while in Great Britain the control of the medical services is exercised to a large extent by the doctors themselves.

> "The demand for medical representation on the administrative side hits at the heart of the matter. There is nothing so highly mystical about the economic and social problems involved as to bar such representation. On the contrary, once the cash and service sides are separated the rest is an extremely simple problem in administration.
>
> "British and French experience, and the judgment of recent official investigators from countries contemplating the introduction of health insurance, gives sound reasons for the conclusion that every step in the direction of separation of these functions and increasing the power of the medical professions in the control of insurance institutions has brought greater satisfaction on the part of patients, public, and practitioners."

The conclusions stated in the two paragraphs quoted above are the result of a penetrating analysis of the methods by which insurance medical services are administered. This analysis, and indeed the whole report, may confidently be recommended to all who are concerned with health insurance, either as practitioners, administrators, or interested members of the general public.

Benefits of Insured Women.

A deputation of women's organisations received at the Ministry of Health on May 25th maintained that the proposal in the National Health Insurance Bill to reduce the benefits of insured women, especially those of married women, was contrary to the basic principle of a State insurance measure, which should involve the pooling of the resources of the scheme for the benefit of all. Whilst admitting that the claims of the women were high, they were not so high as in the case of large groups of insured men against whom no discrimination was contemplated in the Bill, and it was unfair to select one section for a lowering of benefits. The higher sickness rates of women were largely due to their low rates of wages, which in turn were due to the legal and other disadvantages under which so many of them carried on their work. The most equitable way to deal with the position was, not by differentiating women from men, but by equalising the position of men and women; they suggested that there might be a partial pooling of future surpluses, and that the central fund might be strengthened and the powers in respect of the fund increased, or that some other form of reorganisation was necessary. The Minister of Health in reorganising the scheme should give consideration not only to the financial aspects but to the interests of public health.

In reply, Mr. Ernest Brown, Parliamentary Secretary to the Ministry, said that differentiation between men and women was a principle which had been in force since the inception of the scheme in 1911. If the deficiency on the women's side had been met by adjusting men's benefits as well as women's, the aggregate hardship to married women would be much greater, since the vast majority of them, being uninsured, would be affected by any change in their husbands' cash benefits, whereas only the minority of married women—namely, those who were insured (a sixth of the whole) were affected by the proposals in the Bill. He was afraid that the central fund was not nearly large enough to meet the losses arising from the claims of women; a further levy to augment the fund would only increase the number of societies in deficiency. In those circumstances, he said, the only practical alternative to changing the rates of women's benefits was to raise women's contributions by not less than 1½*d.* a week, and the Government had decided that this was an extra burden which they could not ask Parliament to impose.

Points from Committees.

At a meeting of the LONDON INSURANCE COMMITTEE on May 26th Lady Stewart made an appeal to support the claim of women not to have their sickness benefit reduced. There was, however, not much support for this contention, as it was stated that it was largely to protect the contributions of single women—some four millions in number—against the excessive claims of the married—about one million—that the Bill had been introduced. It was suggested that the part-time married woman worker was the chief cause of the heavy sickness claims. The Committee refused by a large majority to express regret at the proposed reduction.

The Committee discussed the question of cuts in the salaries of its staff, and referred the matter back to their general purposes committee, with the suggestion that it was probably better to make some cuts themselves rather than have a cut imposed.

The chairman of the pharmaceutical subcommittee gave a word of praise to the chemists in the area on the accuracy of their dispensing. Of the last 61 tests made by taking prescriptions to chemists and having the results analysed, it was only found necessary, he said, to investigate further in two cases.

The ointment box, cardboard or chip, is liable to give trouble to chemists. Two cases were referred back by the Ministry to the Committee with the suggestion that fines should be imposed for failure to supply 2 oz. and 1 oz. of ointment as required. The chemists had filled a reputed 2 oz./1 oz. box, but the weight was deficient. The regulations provide that the ointment ordered should be weighed and placed in a suitable vessel, and it was decided to inflict fines as suggested.

BIRMINGHAM insurance practitioners are not all business men. Witness two items on the May agenda of the insurance committee:—

> "To approve issue of cheques amounting to £30 13*s.* 7*d.* to insurance practitioner and a chemist in the place of cheques for a similar amount which had been lost. . . ."
>
> "To cancel cheques amounting to £740 6*s.* 8*d.* issued to general practitioners and not presented for payment within three months of issue. . . ."

From figures given it appears that for two recent quarters the number of medical cards issued exceeded the doctors' acceptances by more than 7500, with a total of 20,000 odd. The difference is presumably due to insured persons not taking the cards to doctors for acceptance upon receipt, and possibly to some delay on the part of the doctors in sending up new medical cards when received.

The number of insured persons in the Birmingham area on Jan. 1st, 1932, was 450,166; on April 1st, 453,843.

The CHESHIRE PANEL COMMITTEE had referred to them by the insurance committee a curious claim by a doctor for emergency treatment fees on account of a patient on his list who was attended by himself in an adjacent area, the doctor being also on the panel for that area. The Committee at first declined to pay these emergency fees, and consulted the Insurance Acts Committee. The reply received was that emergency attendance on a doctor's own patient outside the committee's area, but in an area in which the doctor is also on the panel, should be paid for.

During the last financial year a sum of £1056 was received by voluntary levy on insurance doctors, and donations were made as follow: Royal Medical Benevolent Fund and Epsom College, each £52 10*s.*; National Insurance Defence Fund, £200.

At a recent meeting of this Committee the question of a general pension and insurance scheme for insurance

PANEL AND CONTRACT PRACTICE

Health Insurance: An American View.

IN 1930 the American Dental Association decided to make, with the assistance of the American College of Dentists, an investigation into the operation of health insurance in Europe, the object being to produce an impartial study that would "assist in the appraisal of health insurance as a device for meeting the costs of medical care for the underpaid section of American society." The Association were fortunate in securing the services of two highly competent investigators, Mr. A. M. Simons and Dr. Nathan Sinai, who began their work by a study of the printed material available in the United States, and that which could most easily be obtained from abroad, and continued by personal inquiries in England, Scotland, Germany, France, Belgium, Denmark, Austria, Switzerland, and Russia. The result of the investigation is a masterly document—informative, critical, and very readable—which cannot fail to interest not only medical and dental practitioners, but also all persons who care for public health progress.[1] Though the report is informative to a high degree its main concern is not to describe insurance institutions and regulations, but to focus attention "upon the way in which insurance operates and the effects of that operation upon the human beings involved."

The authors maintain that compulsory health insurance, like other forms of social insurance, is a result of industrialisation and low wages; that "the dominant motive in the establishment of every system of health or sickness insurance is the relief of poverty, not the preservation of public health." Health insurance in its inception had for its chief object the payment of cash benefits to compensate the incapacitated worker for the loss of wages. It was a way of inducing the working people to save up for a rainy day, and it was administered by persons whose chief interest was in the economic rather than in the health aspects of social reform. To-day the cash benefits are regarded as relatively less important than the provision of medical care; the chief object is to deal effectively with sickness and to restore lost earning power to the disabled insured workers. Restoration rather than compensation is the modern note, and it finds expression in the provision of medical services that tend continually to increase in range and cost.

GROWING INFLUENCE OF MEDICAL PROFESSION.

This development naturally enhances the importance of the doctors' function in health insurance. And health insurance takes a more prominent part in the doctors' professional activities, for the proportion of the population receiving medical treatment under health insurance schemes tends to increase, not only by additions to the list of insurable occupations, but also by the extension of medical benefit to the dependants of the insured persons. When compulsory insurance was introduced into Germany in 1884 it included not more than about 10 per cent. of the population: now nearly two-thirds of the population receive their medical treatment through the insurance societies. At first, the insurance law seemed of small consequence to the doctors in Germany, who in any case had no organisation which would have enabled them to secure any modification in the provisions of the law affecting medical services. But as the field of compulsory health insurance steadily extended the medical profession became more and more involved with the insurance societies, and though professional organisations were formed they were unable to secure radical alterations in the scheme. Consequently a spirit of antagonism between the profession and the societies developed which has had unfortunate results on the insurance systems.

But with the introduction of the National Insurance Bill into the House of Commons in 1911 a new era began in the history of health insurance. The Bill in its original form reproduced the objectionable features of the German system, but it did not long remain in its original form. Mr. Lloyd George came up against the British Medical Association, at whose insistence the Bill was altered in the things that really mattered to the doctors. It is doubtful if the leaders of the Association at that time fully appreciated the historic importance or the implications of the victory they undoubtedly won for the medical profession. Their example has been followed in other countries. The French insurance law, which established the latest of the European health insurance schemes, was profoundly altered to meet the demands of the medical profession, who in a few months raised a fighting fund of over a million francs and set in motion a wide campaign of public education on the questions of medical service. If compulsory health insurance is introduced into countries, such as the United States, in which it has not yet been established, it will be strange indeed if the doctors allow themselves to be taken unawares.

SEPARATION OF CASH FROM MEDICAL BENEFITS.

According to this report the chief effect of the influence that the medical profession has exercised on health insurance is the separation of the cash benefit side of insurance from the medical services. This has not been effected in Germany, where the insurance societies (*Krankenkassen*) not only collect the contributions and pay the cash benefits, but also employ and control the insurance doctors. In Great Britain the insurance societies were placed in a similar position in the original draft of the Insurance Bill, but the Government were obliged by the opposition of the British Medical Association to create a new local body, the Insurance Committee, to administer medical benefit. In the French insurance scheme the separation of cash benefits and medical service is carried still further, for the insurance doctor is under no contract with a lay administrative body, but is paid direct by his insured patients. The control of medical service is exercised, except in very unusual circumstances, by the medical profession.

The report traces the results that follow upon the separation of the cash benefits from the medical service, the most important being the participation of the medical profession in the administration of the insurance scheme. The report explains in detail what this implies. To begin with, it gives a medical service that works in sympathy with the scheme. These American observers find the German and British health insurance schemes represent "extremes in the degree of medical satisfaction with the position of the profession in the scheme. German physicians are among the most loud in their complaints, and the British apparently are the most satisfied." They cannot attribute this difference of attitude to differences in remuneration, for they find that "allow-cases, a number equivalent to half the births. A postnatal clinic, instituted in 1929, was attended by 103 mothers four or five weeks after delivery, as compared with 65 in the previous year, and arrangements were made to secure the treatment of the large number of abnormalities found. The special efforts to supervise the pre-school child included a full examination of 227 children aged 3 years, 66 per cent. of whom had defects requiring treatment.

Bermondsey.

Dr. D. M. Connan reports that the infant mortality-rate of this metropolitan borough was the lowest recorded and that the cases of diphtheria and scarlet fever were the lowest for 15 and 13 years respectively. Only 15 patients were immunised at the Schick clinic. The general death-rate was lower than in 1930 (13·1) and the pulmonary tuberculosis rate of 1·03 was equal to the lowest recorded—viz., in 1929. The lady almoner makes assessments and collects payments in respect of patients sent to the L.C.C. sanatoriums. In 1931 £400 was collected on 206 assessments. She also found occupation for a number of discharged patients and ran a weekly handicraft class; and her other activities included arranging for convalescent homes for non-tuberculous patients and for health lectures in the schools. The solarium was attended by 677 new cases. The conditions which benefited most were rickets, malnutrition, and debility; while chronic rheumatics obtained decided relief, in the absence of better methods. The group system of irradiation was introduced for schoolchildren. The children march round circles irradiated by mercury-vapour and radiant heat lamps to the music of a gramophone and this is followed by simple physical exercises. Since 1924 the borough council have sent 24 tuberculous patients to Leysin. Of these, 12 are "well and at work"; 4 are "keeping well"; 5 are still at Leysin; 2 have left Bermondsey; and 1 has died from tuberculous meningitis. There were 50 notifications of puerperal fever and pyrexia and the available facilities were used as follows: 41 were admitted to hospital, for 2 a consultant was provided, and for 2 a nurse, whilst there was no application for bacteriological examination.

A full account is given of Bermondsey's housing problem and the efforts being made for its solution. Most of the inhabitants are manual workers and much of the labour is casual in this riverside borough. The houses of former well-to-do residents have been split up into tenements without proper provision for cooking, washing, &c. Many of the 4-, 5-, and 6-roomed cottages, the prevailing type, are occupied by two or more families, and it is difficult to decide how widely to apply registration under the by-laws for houses-let-in-lodgings. There are blocks of flats, including 4000 separate tenements, one or two of the older blocks being "very far from satisfactory." Most of the house property is from 70 to 150 years old and a considerable proportion is worn out. Rents range from 5*s.* per week for one room to 35*s.* for six rooms. This rent is high, says Dr. Connan, considering that the average wage in the borough is from 42*s.* to 45*s.*; and it is often exorbitant in view of the accommodation provided. Since 1919 the Council have had in hand unhealthy areas involving about 650 houses and over 4000 persons, and have rehoused 350 families; the L.C.C. have erected 151 flats; and private enterprise has provided 22 houses and 58 flats. In their five-year programme the Council hope to deal with 22 additional small "clearance" areas and some 40 houses by demolition orders leaving "improvement" areas to the L.C.C. Dr. Connan believes that every available site has been considered by the Housing Committee. The overcrowded families desiring local accommodation number 1180 and those willing to move to L.C.C. estates 295. When a family moves to a L.C.C. estate, efforts are made to prevent overcrowding in the vacated house, but difficulties arise when unemployment causes the moved family to return and overcrowd their relatives in the borough.

Dr. Connan notes a considerable increase in the amount of food, especially bacon, arriving at the borough wharves, necessitating much night inspection. There is a sale for Grade A (T.T) milk, but the price of Certified milk is prohibitive and Dr. Connan does not favour the steadily increasing sale for sterilised milk.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 21ST, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 56 (last week 76); scarlet fever, 1404; diphtheria, 671; enteric fever, 29; acute pneumonia (primary or influenzal), 918; puerperal fever, 45; puerperal pyrexia, 126; cerebro-spinal fever, 46; acute poliomyelitis, 1; encephalitis lethargica, 14; dysentery, 14; ophthalmia neonatorum, 80. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 24th–25th was as follows: Small-pox, 89 under treatment, 5 under observation (last week 116 and 4 respectively); scarlet fever, 1549; diphtheria, 1319; enteric fever, 7; measles, 2550; whooping-cough, 399; puerperal fever, 16 (plus 5 babies); encephalitis lethargica, 228; poliomyelitis, 3; "other diseases," 86. At St. Margaret's Hospital there were 15 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 84 (37) from measles, 9 (6) from scarlet fever, 43 (15) from whooping-cough, 26 (6) from diphtheria, 42 (10) from diarrhœa and enteritis under two years, and 42 (5) from influenza. The figures in parentheses are those for London itself.

Manchester reported the only fatal case of enteric fever. Liverpool reported 16 deaths from measles, Walthamstow, Leeds, and Manchester each 3. Four fatal cases of whooping-cough were reported from Liverpool, 3 from Birmingham. Diphtheria accounted for 8 deaths at Liverpool.

The number of stillbirths notified during the week was 264 (corresponding to a rate of 43 per 1000 total births), including 40 in London.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES.—At the recent annual meeting Lord Chesterfield, who presided, remarked that there is still no accommodation for small children, and that arrangements will presently have to be made for paying patients. There is no isolation or observation ward and the out-patient department is congested. Since it is impossible to enlarge the present building in Leicester-square a new out-patients' department will sooner or later have to be provided in some other central part of London.

ST. BARTHOLOMEW'S HOSPITAL: ANNUAL REPORT.—In 1931 the new in-patients numbered 11,162 and their average stay was 20·9 days: new out-patients were 95,121. In-patients from outside the county of London were nearly 42 per cent. of the total—figures which, the annual report points out, tend to show the national character of the hospital. While there was an appreciable increase in the in-patients, there was a slight fall in the attendances of out-patients and in casualties, and it is anticipated that there will be a further decrease as the result of the recent decision of the governors that national health insurance patients, other than cases of accident or emergency, will not be treated unless they produce a letter from a panel doctor. The income at £224,534 shows an increase of £8170, although donations and subscriptions have declined. The expenditure was £216,370, a decrease of £2770. Considerable economies have been produced as the result of the work of a special committee. In response to representations from the Medical College of the hospital as to the necessity of securing additional facilities for the training of students in obstetrics negotiations are proceeding for amalgamating with a maternity hospital. It is proposed also to absorb the Royal General Dispensary which occupies a corner site on the east side of Bartholomew Close, and the Charity Commissioners have accordingly prepared a draft scheme which, in its final form, is to be recommended to the governors for acceptance.

practitioners came up for discussion. The clerk to the insurance committee had been requested by an assurance society to act in accordance with an authority made by an insurance practitioner to deduct certain moneys from fees due to him quarterly, and pay the same to the assurance society, and the insurance committee resolved to defer action until a report was received from the panel committee. When the matter came later before the drugs committee a letter was read from the deputy medical secretary of the B.M.A. stating that a subcommittee of the Insurance Acts Committee was investigating pensions schemes, and asking the panel committee to hold its hand. This was agreed to.

PUBLIC HEALTH SERVICES

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1931 statistics of two county boroughs and one metropolitan borough :—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 live births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.
Sunderland .. (187,600)	21·8	11·4	1·42	1 20	3·0	1·8	99/36	66	4·6
Bootle .. .. (77,160)	21·6	14·8	1·59	1·46	3·4	1·6	95/41	43	4·2
Bermondsey .. (112,400)	17 4	12 5	1 16	1·30	2·6	1·7	57/—	22	6·1

Registered stillbirths per 100 live births: Sunderland, 3·9; Bootle, 3·8; Bermondsey, 2·5.

Sunderland.

Dr. A. S. Hebblethwaite says the year was not a pleasing one statistically. The general death-rate in the county borough was slightly up and epidemics of measles, influenza, and pneumonia in the first two quarters of the year caused a higher infant mortality-rate. The two-yearly visitation of measles gave rise to 2294 notifications and 108 deaths—a death-rate of 0·57 to be compared with 0·07 for England and Wales. The increased prevalence of cerebro-spinal fever was "shared by the country at large." In Sunderland there were 39 cases and 27 deaths. Difficulty has been experienced in obtaining bacteriological confirmation at an early stage and was reported to the Ministry. Owing to the pressure from other infectious diseases the female ward for tuberculosis had to be used during the later part of the year for scarlet fever, and Dr. Hebblethwaite records an increase of the deaths from pulmonary tuberculosis as additional evidence for the need of more satisfactory institutional accommodation for this disease.

The brightest feature of the year has been the development of the municipal (ex-poor-law) hospital of 415 beds. Additions have been made to the resident and consulting staff. The increase of 20 in the nursing staff has made it possible to defer the waking time of patients to a more satisfactory hour. The accommodation includes tuberculosis wards, a 7-bed ward for school-children suffering from tonsils and adenoids, an electrotherapeutic department, and a 13-bed maternity wing, which admits an increasing number of confinement cases. Critics of the increased cost are reminded that 75 per cent. of the admissions are acute cases, as against 25 per cent. in previous years. The percentage of beds occupied by children during 1931 was 41·6; and 62 private patients were admitted for an average stay of 30·9 days. The surgical beds have been increased and on August 1st an out-patient department was opened. Operations numbered 763 as against 197 in the previous year. General practitioners send in cases after consultation with the medical superintendent, but necessitous cases are admitted through the relieving officers and district medical officers. The greatest need appears to be a hostel for the nurses, who are at present accommodated in temporary huts.

Housing has been a difficult problem. The municipal houses do not house the people who most require re-housing and "these latter have taken the remedy in their own hands by occupying tenemented property in the best residential parts of the town." The new houses erected numbered 520 (including 371 municipal), as compared with 756 in the previous year. A voluntary housing association does useful work by buying and reconditioning and letting at low rentals; and their supervision of their tenants has led to much improved conditions. A second swimming bath is nearing completion, with modern chlorination and filtration, but with this addition, says Dr. Hebblethwaite, provision for swimming will still be inadequate.

Bootle.

Dr. F. T. H. Wood reports a rise in the death-rate of the county borough, due to respiratory disease and influenza in the first quarter. The infant mortality-rate was 16 points up, largely owing to neonatal deaths which were the highest since 1911. The accommodation at the Isolation Hospital was severely taxed by a high incidence of diphtheria and scarlet fever. Plans for a new 45-bed pavilion and an extension of the nurses' quarters were approved in July, but, at the request of the Ministry for economic reasons, a 12-bed cubicle pavilion is to be erected as a first instalment. The recent census enumeration showing a net increase of only 312 was a surprise, indicating large unsuspected emigration. During the corresponding intercensal period the excess of births over deaths was 8548.

In 1921 the population of Bootle of 76,487 lived in 13,320 houses, equivalent to 5·64 persons per house; whereas in 1931 the population of 76,799 lived in 15,391 houses, equivalent to 4·98 persons per house. The 1700 new municipal houses in the Orrell area have absorbed some 9000 people; and there were only 8726 persons living more than two to a room, the usual standard for overcrowding, in 1921. On the other hand there have been 1228 applications for municipal houses since February, 1931, from Bootle residents living in rooms and the particulars of their families suggest considerable overcrowding. Dr. Wood refers to the smaller size of the families nowadays and the praiseworthy demand for a higher standard of living in explanation of these somewhat anomalous figures and he is quite clear "that, however gratifying recent achievements have been, the end of municipal housebuilding is not yet in sight." Good progress was made in the reconditioning of 275 unfit houses, 36 of which were in an "improvement" area. With very few exceptions the schedules of repairs needed were accepted by the owners without modification or the service of statutory notices. The new by-laws for houses-let-in-lodgings, approved on May 19th, 1931, which require the owner to provide for each occupying family adequate and readily accessible w.c. accommodation, domestic water-supply and accommodation for washing clothes, for the storage of food, and for the preparation and cooking of food, are being put in force vigorously.

The antenatal clinics were attended by 748 new benefit, thus relieving the sickness benefit funds of a big percentage of claims due to pregnancy and associated diseases. This latter suggestion would considerably ease the burden of doctors, insured persons, and agents of approved societies who have to decide whether the pregnancy claim is indeed a sickness claim. I have to point out that the National Health Insurance Act provides a sickness and maternity benefit, but there is no money for payment of a pregnancy benefit as such. Hence some of the claims paid at present are obtained by various subterfuges. So the question I ask is: Will the present holders of these surplus moneys prove willing to make such a beau geste? I am not optimistic enough to think so. Compulsory legislation then to take away surplus—but who is going to initiate such an unpopular Bill?

The *contingencies fund* (central fund of societies) referred to by Dr. Walker has been so repeatedly drawn on that it has resulted in present proposals to reduce benefits. The limit has been reached.

Finally we come to the question of an *additional levy*, and here I see Dr. Jane Walker and I are in some agreement, but she is bolder than I, for she demands a levy on all insured persons and I only go by the actuarial calculation—i.e., ½*d.* per insured woman and small reduction of sickness and disablement benefit. I can only reiterate that I support this last method because I believe it is sound finance, and I think the married women get a fair return for their contributions. I repeat that the National Health Insurance Act is an insurance scheme and must have limitations, and I dislike attempts to make insured women recipients of a dole or a charity on the lines of the present unemployment fund.

I can see no justification in the final paragraph for the statement "the lower sickness and unemployment benefits payable to women are a further cause of her greater sickness." If this were true it would follow that medical benefit and all other benefits provided under the National Health Insurance Acts are of no use; and the sooner they are abandoned the better for all. Experience of panel practice lends no support to these statements. No one to-day would seriously suggest the abolition of the National Health Insurance scheme. It is well embedded in our social organisation after 20 years' experience of its value. We await further developments along insurance lines when the state of national finances will permit. Then perhaps dependents may be brought within its scope. I must regretfully maintain that in the interest of a properly regulated finance, and to be fair to all contributors, there must at least be a temporary reduction of sickness and disablement benefits to married women.

I am, Sir, yours faithfully,

Plymouth, May 31st, 1932. MABEL L. RAMSAY.

TOXIC EFFECTS OF PHENOLPHTHALEIN.

To the Editor of THE LANCET.

SIR,—In his letter on this subject in your issue of May 7th (p. 1015) Dr. Aubrey lays himself open to the same criticism which he makes on the letter of Dr. Hunt in a previous issue. He remarks on the want of information about the dosage of phenolphthalein producing toxic symptoms, but he gives none himself in the cases he describes. No reference has been made in this correspondence so far to the description by Lauze in 1924 of cases of uræmia, of general collapse, and of severe purpura after the administration of this drug. In the first of two new cases which he described in the *Clinical Journal* severe vertigo, cyanosis, hæmorrhagic stools, and severe faintness were noted on five separate occasions but he also omitted to state the dose given. In the second case in a man of 60, which was similar and equally severe, the onset followed a few hours after taking a medicated cocoa containing only 0·1 g. of phenolphthalein. Extensive purpura was present in each case.

I am, Sir, yours faithfully,

C. E. LOWE, M.R.C.S. Eng.

Heswall-on-Dee, Cheshire, May 24th, 1932.

THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

To the Editor of THE LANCET.

SIR,—Knowing as I do that the court of governors of the University of Durham College of Medicine have decided to institute an inquiry into the administration of the College, and that that decision was largely influenced by doubts as to the wisdom and justice of the action of the Council with regard to the personnel of the department of bacteriology, I am astonished to observe that the Council are now advertising for a professor of bacteriology. In these circumstances I venture to suggest that it would be well that any prospective candidate should make himself familiar with the present condition of affairs in the College, and should scrutinise carefully the terms and conditions of the appointment.

I am, Sir, yours faithfully,

RUTHERFORD MORISON,

Emeritus Professor of Surgery, Durham University.

St. Boswells-on-Tweed, May 24th, 1932.

FREE TREATMENT AT VENEREAL CLINICS.

To the Editor of THE LANCET.

SIR,—The daily press anticipates that drastic economies in the social services will be carried out before the end of the year. Scope for such economies without danger to the national health would appear to lie in reducing the expenditure on venereal clinics. At present persons who can well afford private treatment attend such clinics and the curious position obtains that the only diseases in which, in the great majority of cases, infection is due to a voluntary act of the patient are also the only diseases accepted at clinics for treatment without any inquiry as to the patient's income or financial ability to pay for private treatment. As a result of this special privilege of the patient suffering from venereal disease, the practice of many venereal specialists has decreased almost to vanishing point, so that the State loses their income-tax in addition to the money voted from public funds for the maintenance of unnecessarily large and numerous V.D. clinics.

The venereal specialist sees ruin staring him in the face, as with the universal financial stringency more and more patients go to clinics who do not properly belong to the hospital class, and who can even with their reduced incomes well afford a moderate fee for private treatment. If free, or nearly free, treatment at V.D. clinics was restricted to married persons with incomes below £300, or unmarried adults with incomes not exceeding £150, both the State and the venereal specialist would benefit and the health of the country would not be risked to the slightest degree. I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Harley-street, W., May 25th, 1932.

CORRESPONDENCE

APPENDICITIS.

To the Editor of THE LANCET.

SIR,—Sir James Berry has done a service to medicine by emphasising the need for a conservative attitude in dealing with appendicitis with abscess. On the other hand it would be disastrous if his advice was taken to apply to all cases of acute disease of the appendix.

Over 3000 persons die in this country every year of acute appendicular disease. A few of these are the victims of ill-advised and meddlesome surgery. The vast majority of the fatalities, however, are in cases of acute appendicular obstruction, a disease differing essentially in its pathology and in its clinical symptoms from primary inflammation of the appendix.

Since 1914 I have sought to obtain recognition of this acute form of intestinal obstruction as an entity. It differs from acute inflammation of the appendix in the vital factor of tension of decomposing fæcal matter within the lumen of the organ leading to gangrene and perforation before protective adhesions have had time to form. Colicky pain, and usually vomiting, but no fever or acceleration of pulse-rate, distinguish its onset and, when diagnosed, immediate operation is imperative. If the obstructive cases are dealt with promptly, we shall not have to deplore a mortality figure which represents a needless sacrifice of useful lives. The inflammatory and localised suppurative types of case may safely be treated with conservatism and restraint.

What is most needed is the education of the public to the fact that abdominal colic demands medical advice *and not purgation*; that a dose of castor oil, administered for an undiagnosed abdominal pain, may be lethal. We owe it to the public, however, to be able to distinguish the dangerous condition when it is present and this we can only do if we have a clear understanding of the underlying pathology.

I am, Sir, yours faithfully,

Edinburgh, May 24th, 1932. D. P. D. WILKIE.

To the Editor of THE LANCET.

SIR,—By his timely and wise remarks Sir James Berry has done a real service to surgery. I share his doubts as to whether, from the point of view of the *patient*, the progress of surgery has been as beneficial as it might have been. I am in cordial agreement with his criticism of the teaching that every case of acute appendicitis requires immediate operation, and I write this with the greater pleasure, inasmuch as in this matter I have not always seen eye to eye with my respected former teacher. Now I admit readily that he was right and I was wrong.

For many years I have taught that in abdominal surgery success depends very largely on adequate preparation of the patient. This, I am convinced, is no less true in dealing with cases of acute appendicitis. A delay of some hours spent in preparatory treatment not only ensures a safer operation, but in the majority of cases brings about such an alleviation of the symptoms that operation can be delayed until the acute stage is passed. Shortly after the war I began the practice of delaying operation in all cases of acute appendicitis for six or eight hours, so as to allow time for the patient to have rectal injections of saline and glucose, and sodium bicarbonate by the mouth. I was surprised to find how frequently the symptoms subsided, so that in some cases operation was not necessary at all and, in the majority operation could be deferred for four or six weeks.

I have no doubt that Sir James Berry is right when he says that there is a greatly exaggerated idea about the mortality of appendicitis when properly treated on common-sense lines. Doubtless some cases do necessitate prompt operation, but they form the minority. Perforation of the appendix is obviously an indication for operation, but we must remember that even general septic peritonitis is not inevitably fatal. Further, even when we suspect perforation and operate, we are sometimes surprised to find that nature has localised the pus, so that operation might have been postponed. I admit that, in the hands of an expert, operation during the acute stage is relatively safe, but an expert is not always available, and I believe that if the precepts of Sir James Berry were followed more generally, the mortality of acute appendicitis would be reduced greatly.

I would however point out, first, that the "delayed treatment" should be carried out only when the *patient is in a nursing home or* hospital, where immediate operation can be performed if the occasion should arise. Secondly, Lord Moynihan pointed out many years ago the grave risk of perforation which attends the administration of purgatives. I have verified the truth of this warning on many occasions. When purgatives have been administered, especially in children, only prompt measures will prevent the catastrophic effects of the injudicious misuse of castor oil.

There is no doubt that, as Lord Moynihan so aptly says, "Deaths are too often 'therapeutic,' caused, that is, by the active measures designed for relief." Even in modern surgery there is room for clinical judgment and common sense, whereas the policy too often adopted is the easier but more dangerous one of "Look and see."

I am, Sir, yours faithfully,

HERBERT J. PATERSON.

London, W., May 28th, 1932.

REDUCTION OF BENEFITS OF INSURED WOMEN.

To the Editor of THE LANCET.

SIR,—It is always well to have the two sides of a question presented, and Dr. Jane Walker has ably presented the case in favour of non-reduction of insurance benefits for married women. So I will just make comments on her letter.

The *unemployment benefit fund* began well as an insurance scheme. It is no longer a well-organised insurance scheme. It has completely broken down on its insurance side and contributions are in no way equivalent to benefits given. It is a national dole with consequent very heavy charges on the national exchequer, and attempts are now being made to restrict it to its original intention by the means test and in other ways.

Use of surplus moneys.—If the approved societies and the 88 per cent. of men and 38 per cent. of women beneficiaries would give consent to alienate say 2½ million pounds of their quinquennial valuation and give it to the Government, the yearly deficit of £420,000 for the married women's claims pay for the next five years could doubtless be met, or alternatively give the same amount to initiate what really would be much more useful—*viz.*, a statutory pregnancy

TOXÆMIA OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—I read with interest your leading article (May 21st, p. 1101) and note that H. J. Stander concludes that calcium therapy is not a rational measure in eclampsia. Similarly D. F. Anderson found that calcium gluconate had no abrupt effect on the frequency of fits. In a case of eclampsia, described in your columns,[1] I produced a definite hypercalcæmia, the serum calcium being 13·9 mg. per 100 c.cm. serum, and still the convulsions persisted. That calcium is not a panacea in pregnancy toxæmia is obvious. Thrombosis is a predominant feature in eclampsia and it seems somewhat irrational to administer a drug which increases the coagulability of the blood.

I am, Sir, yours faithfully,
W. C. W. NIXON, M.B., F.R.C.S.
St. Mary's Hospital, W., May 30th, 1932.

---

[1] THE LANCET, 1931, ii., 291.

SPONTANEOUS LACTATION.

To the Editor of THE LANCET.

SIR,—I have read with interest in your issue of April 30th (p. 928) Dr. Krestin's paper on Spontaneous Lactation with its full bibliography. May I add some quotations on the subject from ancient Jewish literature. In the Talmud, which dates from about the second century, we find in Tract "Sabbath" p. 53, the following story:—

> "It happened with one whose wife died and had left a suckling infant and the father had no means to provide for a nurse, then miraculously two nipples, like those of a woman, have opened from him and so he himself nursed his son. Rabbi Joseph said: 'Behold what great a man he is that such a miracle occured with him.' Abayê argued: 'No, on the contrary, what a bad man he is, that for his sake nature has had to deviate from the fixed laws of creation.'"

In the Bible (Esther, chap. 2, verse 7) we read:—

> "And he brought up Hadassa, that is Esther, his uncle's daughter; for she had neither father nor mother, and the maid was fair and beautiful, whom Mordecai, when her father and mother were dead, took for his own daughter."

This passage is commented by the Talmudic scholars in "Midrash Bereshith Rabah" in a similar way:—"That Mordecai has then developed two mammæ like those of a woman."

I am, Sir, yours faithfully,
M. N. NEUMANN, M.D.,
Physician in charge of the Internal Department of the Bicur-Cholim-Hospital, Jerusalem, Palestine.
May 11th, 1932.

OBITUARY

HERBERT WATNEY, M.D. Camb., F.R.C.P. Lond.,

LATE PHYSICIAN TO ST. GEORGE'S HOSPITAL.

THE death is announced in the eighty-ninth year of his age of Dr. Herbert Watney, the well-known agriculturist.

Herbert Watney was born in 1843, the son of Mr. James Watney, of Haling Park, Surrey, a member of the great brewing firm. He was educated at Rugby and St. John's College, Cambridge, whence he proceeded to St. George's Hospital, on taking up the study of medicine. He graduated at Cambridge as M.B. in 1870, and proceeded to the M.D. in 1876, and, after serving the usual appointments, was elected assistant physician to St. George's Hospital. He was a successful member of the teaching staff and in particular his lectures in the medical school on physiology were valuable to the students. He became full physician to the hospital in 1881, and in 1883 was elected F.R.C.P. and appointed examiner in medicine at Cambridge. But he shortly afterwards retired to an estate which he had bought in Berkshire and which carried with it the manors of Bradfield and Ashampstead. His early retirement from practice led to the discontinuance of physiological work which had promised to be of real significance.

During Dr. Watney's long and busy life as a country land-owner he became well known in agricultural circles as an expert on afforestation and pedigree cattle, while the neighbourhood benefited by an installation of water-supply which he provided at his own expense for the villages adjacent to his property. He married in 1873 Sarah, daughter of the Rev. Marcus Rainsford, who long predeceased him and by whom he had five children. The eldest son was killed in the war, while the second son and two daughters entered the medical profession and have been largely engaged in missionary work in China. Dr. Watney was himself a devoted churchman and a great supporter of foreign missions. As a Cambridge undergraduate he had been a noted oar, rowing for three successive years in the Cambridge boat, and winning the Colquhoun sculls.

WILLIAM DOVE MACFARLANE, M.D. Glasg., F.R.F.P.S. Glasg.,

LATE PROFESSOR OF MIDWIFERY IN ANDERSON'S COLLEGE, GLASGOW.

Prof. Macfarlane, who died at Hunter's Quay on May 6th, made a reputation for himself both as a teacher and organiser, devoting much of his time to the development of the practice of gynæcology and obstetrics in the city of Glasgow.

William Dove Macfarlane was born at Busby, where his father was a medical man. He was educated at the University of Glasgow, and graduated in 1890 as M.B., C.M. He held the usual residential appointments and was for a time resident surgeon in the Victoria Infirmary, Glasgow, after which he was able to enjoy a good deal of post-graduate work through visits to Austria and Germany. On his return from the continent he joined his father in general practice at Busby, and worked there for a considerable period before deciding to specialise in surgery and gynæcology on his election to the staff of the Glasgow Royal Infirmary. There he made a mark for himself immediately as a clinical teacher, and was soon appointed surgeon to the Glasgow Royal Samaritan Hospital, while in 1911 he was invited to fill the chair of midwifery in Anderson's College. So successful was he as an exponent of his subject in lecture room and operating theatre, that his early retirement was received with regret, but in 1920 he resigned both his professorship and his hospital appointments and concentrated upon private practice, and upon the improvement of clinical teaching and the coördination of the various opportunities offered for the study of gynæcology in Glasgow. He was elected to the board of management of the Glasgow Royal Maternity Hospital, and to the Council of the Royal Faculty of Physicians of Glasgow, while he served as president of the Glasgow Obstetrical and

TRAINING IN TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I am interested in Dr. Davidson's letter with regard to instruction in pulmonary tuberculosis, and particularly with regard to his remarks that there is no compulsory teaching in many of the medical schools. The present position of Charing Cross Hospital Medical School is as follows: An out-patient clinic exists under the care of Dr. F. H. Young, and attendance at this is a compulsory part of every student's curriculum. In the in-patient department ample material exists for comprehensive instruction in tuberculosis.

I am, Sir, yours faithfully,

ERIC A. CROOK,

Dean, Charing Cross Hospital Medical School.

May 20th, 1932.

To the Editor of THE LANCET.

SIR,—I wish to support what Dr. Davidson says in his letter in the strongest possible terms. I have the opportunity of being in touch with recently qualified men from two London teaching hospitals. Their lack of knowledge of pulmonary tuberculosis is lamentable, and in addition to the reasons Dr. Davidson has put forward, I think the following are of importance.

Some physicians do not care to have cases of pulmonary tuberculosis in their wards, and the consequence is that a student during his ward clerkship gets very little opportunity of learning and recognising anything except the grossest physical abnormalities in the chest. Secondly, in out-patient teaching the early case of pulmonary tuberculosis who shows little or nothing in the way of abnormal physical signs is demonstrated very infrequently and consequently the student does not realise that acute types of pulmonary tuberculosis may progress very far unless the condition is suspected merely on the history.

In addition the newly qualified man has usually no idea of the facilities made available by public authorities for the free examination of sputa for tubercle bacilli or those offered for residential treatment. A good deal could be done to remedy these failings without adding compulsory attendance at a tuberculosis dispensary to the curriculum, but I doubt whether a knowledge of "after-treatment" is likely to be adequately taught except in the latter.

I am, Sir, yours faithfully,

Harley-street, W., May 19th, 1932. F. H. YOUNG, M.D.

OBESITY FOLLOWING SUBARACHNOID HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—The cases of spontaneous subarachnoid hæmorrhage described by Prof. A. J. Hall in your last issue are of particular interest to me, as I was in attendance on Case 3. In certain aspects this case differed from the others described, and as she removed shortly after the first attack and Dr. Hall lost sight of her, he will, I have no doubt, be interested in the subsequent events. After the first attack in December, 1926, the patient remained well for four months. She then had severe left-sided headaches for five weeks, followed by an attack of more violent epileptiform convulsions. During a brief interval in one of these attacks the face became almost black, breathing stopped, and I thought she was dead. Artificial respiration was done and the breathing started again. Evidently at this moment the hæmorrhage must have been pressing on the vital centres at the base of the brain and paralysing the respiratory area. For the next four weeks the temperature varied from 99° to 103° F. Recovery then ensued with the development of obesity, so that in a comparatively short period the patient put on 3 st. in weight.

The points in this case I wish to emphasise are the prolonged high temperature, the large hæmorrhage despite which the patient recovered, and the obesity. Dr. Adie who also saw this case told me he had never observed this condition before. Laboratory tests in this patient showed the urea concentration normal, sugar tolerance normal, basal metabolic rate normal, a negative Wassermann. The menses were normal. X ray examination showed skull sinuses clear, and the pituitary fossa of a normal size and shape; no other clinical evidence of pituitary disease. Now comes the interesting question. What is the cause of this abnormal increase of fat in spontaneous subarachnoid hæmorrhage? Despite the laboratory findings, I suggest the obesity is due to some damage, irritation, or derangement of the pituitary gland or its stalk. This seems to me the only possible explanation. Apart from the obesity the patient is now in fairly good health.

I am, Sir, yours faithfully,

JOHN R. O'BRIEN, M.D., L.R.C.P.

Hull, May 28th, 1932.

PUERPERAL SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—Prof. Okell, in his third Milroy lecture which appeared in your issue of April 23rd, inquires whether the early rash in cases of so-called surgical scarlet fever gives a positive Schultz-Charlton reaction. A recent case of puerperal fever, accompanied by a profuse scarlet rash, which I was called to see, certainly did.

The case, which was under the care of Dr. Olive Coldicott, of Grinshilll, had an easy breech delivery on April 26th. Two days before this a child had returned to the house from hospital, suffering from a still discharging abscess of the neck, stated to be a streptococcal infection. On the 29th the woman's temperature shot up, and a "scarlet" rash developed. There was no sore-throat or vomiting. When seen by me on May 2nd the pulse was 132, temperature 103·6° F., and there was a thick universal scarlet rash. There was a condition of marked euphoria, with bright eyes, and alert mental condition. No signs on fauces, tonsils, or tongue. Uterine involution was sluggish, and lochia not offensive. No other physical signs per vaginam or elsewhere. A Schultz-Charlton test had been performed by Dr. Coldicott, and was strongly positive.

In view of the possibility of this patient infecting others with frank scarlet fever (probably an unnecessary apprehension) I arranged for her removal to the ordinary fever hospital. Here she was under the care of Dr. A. D. Symons, and was given hot vaginal douches, under the influence of which a thick purulent discharge began to come away. I was asked to see her again on May 3rd, and gave her glycerin drainage by the Remington Hobbs method. There was no doubt as to the profuse uterine discharge, or the puerperal nature of the rash, probably contracted from the child returned from hospital.

The patient was severely ill for some days, and was given several injections of antiscarlet serum. She also exhibited some pleurisy at one base, but eventually made a complete recovery.

I am, Sir, yours faithfully,

R. L. E. DOWNER, M.D. Lond., M.C.O.G.

Shrewsbury, May 28th, 1932.

1931, and on April 30th, 1932.—Sir E. Hilton Young replied: The number of persons (men, women, and children) in receipt of poor relief in England and Wales (excluding rate-aided patients in mental hospitals, persons in receipt of domiciliary medical relief only, and casuals) on Saturday, April 25th, 1931, and on Saturday, April 30th, 1932, were 1,003,700 and 1,195,038 respectively.

THURSDAY, MAY 26TH.

The Sale of Disinfectants.

Mr. Glossop asked the Home Secretary if his attention had been called to the result of a High Court appeal which had brought to light new facts relating to the sale of disinfectants; and whether he would consider the introduction of legislation to revise the existing Poison and Pharmacy Acts.—Sir Herbert Samuel replied: Yes, Sir, and on the question of fresh legislation to deal with the sale of disinfectants. I would refer the hon. Member to the answer which I gave to a question on March 24th.

[In replying to a question of Captain Elliston on March 24th the Home Secretary stated that the introduction of the Poisons and Pharmacy Bill, 1931, again next session would be considered in due course.]

Mr. Glossop asked the Minister of Health if any steps could be taken, in view of the present position of maternal mortality, to warn the public of the danger of using lysol and other disinfectants sold at cheap stores in such a diluted form that when diluted in accordance with usual practice they were useless; and if he would take steps to prevent the sale of such diluted disinfectants.—Sir E. Hilton Young replied: I propose to await the final report of the Maternal Mortality Committee which will, I understand, include observations on the subject of the use of lysol in midwifery. I have no power under the existing law to take such steps as are suggested in the second part of the question.

Boneless Meat and Public Health.

Captain Ramsay asked the Minister of Health whether the public health officials were able to carry out satisfactory tests in regard to the boneless meat not in carcass form imported into this country, in view of the fact that the internal organs wherein frequently the only traces of disease existed had been removed from such meat.—Sir Hilton Young replied: I am advised that while it may be possible to detect disease in boneless meat, the only satisfactory way of ascertaining that meat is free from disease is by inspection of the whole carcass at the time of slaughter. I am accordingly proposing to amend the Imported Food Regulations so as to require an official certificate of inspection with any imported meat less than the whole of the carcass. I am sending my hon. and gallant friend a copy of the existing regulations and the draft amending regulations.

Psittacosis and Parrot Importation.

Mr. Temple Morris asked the Minister of Health whether in view of the fact that no case of psittacosis had been reported in Argentina for over a year and the inconvenience the present restriction on the importation of parrots was causing the public, he could see his way to modify the present regulations regarding the introduction of parrots into this country.—Sir E. Hilton Young replied: This question is receiving continuous attention in my department in the light of all the information available on the subject, but I am not satisfied that the risk of the spread of psittacosis through the importation of parrots has so far diminished that the restrictions on their importation, which apply generally and not only to Argentina, could safely be relaxed at present.

Economy in Local Government Expenditure.

Mr. Hall Caine asked the Minister of Health whether his department would refrain from pressing the different local authorities to carry out all statutory duties imposed upon them which these local authorities might consider might usefully be postponed in view of the economic situation of the country.—Sir E. Hilton Young replied: The reduction of local expenditure was dealt with in a circular issued last September. The action of my department is in accordance with the principles laid down in that circular, which whilst deprecating a wholesale course of cutting down expenditure whatever be its purpose, requires the careful scrutiny of the whole field of expenditure made necessary by the financial situation.

Butter-fat Content of Tinned Cream.

Sir Charles Cayzer asked the Minister of Health whether his attention had been called to the recent report of the Walsall borough analyst with regard to imported cream sold in tins, which was stated in such report to contain only 22 per cent. of butter-fat as against the usual 50 per cent. in fresh cream; and whether he would consider the introduction at an early date of regulations to provide that all tinned cream should bear a label stating the precise butter-fat content of the cream therein.—Sir E. Hilton Young replied: I am aware of the report referred to. I have no power to make regulations for the purpose suggested, but I have taken note of the matter in connexion with other representations which have been made as to the composition and labelling of articles of food.

Tuberculosis Grants.

Mr. West Russell asked the Minister of Health what were the total sums expended by the Exchequer in respect of tuberculosis in each of the seven years 1924 to 1930: were the sums expended conditional upon proportional expenditure by local authorities: and, if so, what were the proportional terms.—Sir E. Hilton Young replied: The grants made by my department for this purpose were as follow:—

1. *Grants towards the expenditure incurred by local authorities on the treatment of tuberculosis.*

Year.	£	Year.	£
1923–4	1,336,741	1927–8	1,710,248
1924–5	1,430,407	1928–9	1,752,112
1925–6	1,546,828	1929–30....	1,820,144
1926–7	1,631,169		

These grants included (1) a fixed annual grant of £340,788 in lieu of the sums previously available for the treatment of insured persons out of funds provided under the National Health Insurance Acts; (2) a grant equal to 50 per cent. of the approved net expenditure of local authorities on the treatment of tuberculosis after deducting the fixed grant.

2. *Capital grants in aid of the erection or extension of institutions for the residential treatment of tuberculosis.*

Year.	£	Year.	£
1923–4	87,070	1927–8	27,320
1924–5	14,521	1928–9	29,409
1925–6	18,679	1929–30	25,496
1926–7	18,203		

These grants were made at the rate of £180 per bed, subject to a limit of three-fifths of the total cost.

Staff of Ministry of Health.

Colonel Gretton asked the Minister of Health what was the number of the staff employed in the Local Government Board in 1913 and the total of their salaries in that year; and what was the number of the staff employed by the Ministry of Health in the past year 1931 and the total of the salaries paid in that year.—Sir E. Hilton Young replied: The Local Government Board staff in 1913 numbered 947: the expenditure on salaries was £250,846. The staff of my department in 1931 was 6464 with a salary cost of £1,850,972.

MONDAY, MAY 30TH.

Contagious Abortion in Cattle.

Lord Scone asked the Minister of Agriculture what steps were being taken to eradicate epizootic abortion in cattle.—Sir J. Gilmour replied: Contagious abortion in cattle has not been made a notifiable disease as it does not lend itself to legislative control. Veterinary research has, however, made available a reliable test by which affected animals can be detected, and also an immunising agent suitable for use in heavily infected herds. As I have already announced, the Government is undertaking an investigation into the means of securing a reduction of disease amongst dairy herds, and contagious abortion is one of the diseases included in this inquiry.

A Driving Test for Motorists.

Mr. Remer asked the Minister of Transport if he would introduce legislation requiring motorists to undergo a driving test before being granted a licence and requiring all cyclists to be registered.—Mr. Pybus replied: The Road Traffic Act, 1930, already empowers me to prescribe a test for applicants for driving licences suffering from certain physical disabilities, and a driving test for this purpose has been prescribed. The question whether there should be a general driving test was discussed at considerable length during the passing of the Bill, and I should not feel justified in introducing amending legislation on the point. The cost and inconvenience of requiring all cycles to be registered would, I think, outweigh any advantages that might appear to attach to such a system.

Protection of Pedestrians against Street Accidents.

Sir William Davison asked the Minister of Transport whether his attention had been called to the method adopted by the municipal authorities of Mannheim to make pedestrians realise the risks they incurred by carelessness in

Gynæcological Society and, during the annual meeting of the British Medical Association at Glasgow, was secretary of the section dealing with those subjects. He was the author of "Essentials of Midwifery and Gynæcology, notes for students," published early in his teaching career; of Uterine Fibroids, a study of 150 cases communicated to the *Glasgow Medical Journal*; and of papers on Ovarian Cyst and Retro-displacement of the Uterus, communicated to the *Journal of Obstetrics and Gynæcology*. His papers were clear and practical, but he was an infrequent writer and refused more than one request to produce a text-book, or to collaborate in the production of such a work.

Prof. Macfarlane's death will recall his memory to very many who owe to his instruction lessons of the highest professional value, for he was a great teacher.

THOMAS FAWSITT, M.B.E., M.R.C.S. Eng.

Dr. Fawsitt was sincerely respected in Oldham, to which he gave his whole professional life, and his death at the age of 86 brings back memories of a long career of service. Born in the town, the son of Dr. Thomas Fawsitt, he was sent to Rugby, and there won the good opinion of Dr. Temple, afterwards Archbishop of Canterbury, who recommended that he should enter the Church. This advice was not taken, however, and Fawsitt, at the age of 17, was apprenticed to his uncle—who had taken over the family practice—and attended lectures at the Manchester School of Medicine. Later he went up to Guy's Hospital, whence he qualified in 1867. Returning two years later to become his uncle's partner he was soon a familiar figure in the town. With his white horse—usually tied to a lamp-post—he was ever at the call of all and sundry. "Can you recall anyone who has worked as he has done for the sheer joy of doing it?" asked a colleague when in 1920 the Oldham Medical Society gave a dinner in his honour. "Morning, noon, and night, the whole year round—barring a short three weeks—work has been his absorbing and almost only interest. His early rising has become a byword, likewise his cryptic conversation with garrulous patients, his readiness to respond instantly to a call at any hour—day or night—no matter how inconvenient, and, lastly, his wonderful endurance." When the Oldham Royal Infirmary was opened in 1872 Dr. Fawsitt and Dr. George Thomson were the first members of the staff, and it was not long before the former became the leading surgeon of the town. To the infirmary he remained a constant friend, while his interest in the local nursing association and in the St. John Ambulance Association—he began lecturing for it in 1883—was close and active. In 1922 he received the freedom of the borough, his portrait, and a large monetary testimonial which was handed over to the Royal Infirmary.

By his first marriage Dr. Fawsitt had two children, neither of whom is living. His second wife died a few weeks before him, and he is survived by their son.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

CHILDREN AND YOUNG PERSONS BILL.

MOVING the second reading of this Bill in the House of Lords on Thursday, May 26th, Viscount SNOWDEN, Lord Privy Seal, said the Bill was largely based on the accumulated experience of 24 years' operation of the Children Act of 1908. The publication of the reports of the Children's Branch of the Home Office stimulated public opinion in the problem of the neglected child and that led to the appointment in 1925 of a committee to deal with the question of child welfare. That committee reported in 1927, and the Bill which he now submitted was based very largely on the recommendations of that committee which was known as the Young Offenders' Committee. The Young Offenders' Committee recommended the establishment of special observation centres for children and young persons on remand. The Bill made no provision for setting up such centres. Apart from the objection on principle, it would be impossible in present financial circumstances to embark upon such a costly experiment. The estimated cost of such a centre for London would be £50,000 and the annual cost of maintenance would be over £10,000. But it was hoped that for the time being something might be done to secure the same object by improved remand homes in a number of convenient centres. These places of detention would be transferred to the councils of the counties and the county boroughs, and the Home Secretary would be empowered to inspect these remand homes. These powers would be used to the utmost to provide needed medical observation and examination. It was believed that on these lines for the time being the purpose of observation homes could be met. Dealing with the employment proposals in the Bill Lord Snowden said that under the existing law no child under 12 might be employed, except so far as the employment of children by their parents might be permitted by by-laws. A child between 12 and 14 might not be employed on Sundays for more than two hours. A child between 12 and 14 could not be employed on any day before six in the morning or after eight at night. A child between 12 and 14 might not be employed on any school day before the close of the school. The present Bill proposed to raise the age below which street trading would not be permitted from 14 to 16, subject to a limited exception where children were employed by their parents; and also to raise the age from 16 to 18 below which street trading could be regulated by the local authority. The question of the employment of children in unregulated trades had been before the Home Office and Governments for a great many years. There could be no doubt that it would have been dealt with in this Bill had it not been for the financial crisis and the critical situation of the country.

Lord SANDERSON, on behalf of the opposition, congratulated Lord Snowden on introducing a Bill for the protection of children, but he and his colleagues regretted that there was no mention of observation homes in this Bill. It was pretty generally realised that many of the offences and crimes committed by children were not due to the moral depravity of the child but to physical defects which ought to be discovered and treated.

The motion for the rejection of the Bill was negatived by 38 votes to 5, and the measure was then read a second time.

CLEANSING OF SHELL-FISH BILL.

The Public Health (Cleansing of Shellfish) Bill was read the third time in the House of Commons on May 24th, and was introduced and read a first time in the House of Lords on May 25th.

In the House of Lords on Tuesday, May 31st, the Public Health (Cleansing of Shell-fish) Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, MAY 25TH.

Poor-law Relief.

Mr. LUNN asked the Minister of Health how many persons were receiving poor-law relief in Great Britain on April 30th,

Shopping in Hospitals.

The central public health committee of the London County Council has decided to allow the sale in the Council's hospitals of certain articles during hours and under regulations to be fixed by authority. The articles that may be bought include tobacco and cigarettes, newspapers, books, stationery, and "plain sweets."

North Manchester Free Foot Hospital.

Additional accommodation at this hospital was opened last week. Hitherto it has been treating 100 cases daily, but will now be able to deal with double that number. Twenty-five students are in training.

A Ford Ward at Ilford.

Lady Levita last week opened a new ward of 27 beds at the King George Hospital, Ilford. It has been named after the Ford Motor Company, Limited, which has defrayed the cost, amounting to £10,000 ; its works are in the area served by the hospital.

Belgrave Hospital for Children.

This Clapham-road hospital last year admitted 2313 children, and there were 13,206 out-patients. The former cost £3 1*s.* 3*d.* per week ; each out-patient (61,998 attendances) cost a fraction over 8*s.* 1*d.*

Hospital Openings by the Duchess of York.

On Tuesday last week the Duchess of York opened the new Orthopædic Hospital at Mount Gold, Plymouth. Accommodation is provided for 120 patients (100 children) in three wards, each of which has a solarium, and the cost will be £56,000. On the following day the Duchess opened a new maternity ward at the Royal Northern Hospital, Holloway-road. The ward has been endowed by the Ladies' League, and a tablet unveiled by the Duchess records that it is named the Rosemary Ednam Ward, in memory of the late Viscountess Ednam, who was killed in an aeroplane accident in August, 1930.

Leicester Royal Infirmary.

The annual report, which shows that 1931 ended with a small credit balance after an expenditure of £87,597, records that the number of in-patients, 8912, has doubled in ten years. The casualty department is becoming a serious problem, and much money will presently have to be spent on new buildings. The average stay per patient was 19 3 days, and the average cost per occupied bed £158. In-patients from road accidents cost £2850, of which £484 was recovered. The nurses' quarters are being enlarged, and further extensions of those quarters, costing £50,000, will be undertaken shortly.

Asiatic Society of Bengal.

At a meeting of the medical section of this society, held in Calcutta on April 26th, with Lieut.-Colonel R. Knowles in the chair, Dr. U. N. Brahmachari read a paper on the Treatment of Kala-azar with Intramuscular Injection of Sodium Sulphomethyl Stibanilate. He reported that a series of cases had been treated with doses of 0·2 to 0·4 g. dissolved in 1 to 2 c.cm. of water, and injected intramuscularly twice a week. Effects on the size of the spleen, pyrexia, blood count, and Leishman-Donovan bodies were very satisfactory, and all the patients were cured. There were no local or constitutional symptoms. One patient suffering from albuminuria as a complication was also treated with this compound without ill result, and subsequently recovered. The compound, Dr. Brahmachari said, is obtainable under various names—e.g., Thio-sarmine, Sulfarsenol, and Kharsulfan—and has been successfully used in the treatment of syphilis. Further observations are in progress.

St. George's Hospital.

The annual report states that 4937 patients, 500 of whom were children under 12, were admitted last year, and that 262 infants were born in the hospital. The mean residence was 21·55 days, and 822 patients were sent to Atkinson Morley's Convalescent Hospital. The weekly cost per head was £4 8*s.* 2*d.*, a small reduction ; the cost per bed was £229 18*s.* 11½*d.*, a fall of more than £4 10*s.* New out-patients numbered 37,934 ; their cost per head was a fraction over 7*s.* 7½*d.*, or nearly 1*s.* 7*d.* per visit. The ordinary expenditure was £81,378, a saving of £2447 ; and there was a surplus for the year of £15,766, which was transferred to capital account for reduction of debt. The overdraft, nevertheless, remained at £29,755. A further income of £20,000 is necessary if the activities of the hospital are not eventually to be curtailed. New infant welfare, rheumatism, and orthopædic clinics were started during the year. In the physiotherapy department there were 1817 patients who made on the average 18·87 attendances, which is admitted to appear to be "somewhat high," but it is pointed out that, to be effective, massage must be given frequently and regularly.

Tribute to a Surgeon.

Recently a bronze tablet was unveiled in the main corridor of the Cameron Hospital, West Hartlepool, to the memory of the late Dr. William Gray, who was honorary surgeon to the institution from 1905 to 1931. The tablet, which has been presented by his medical colleagues, the management committee, and staff of the hospital, was unveiled by Dr. A. V. Macgregor, the senior member of the honorary medical staff. It was on Dr. Gray's initiative that the orthopædic department of the hospital was established.

University College Hospital.

In 1931 there was a fall of 461 in the number of in-patients, and of more than 4500 in the out-patients, but the in-patients stayed longer. There was also a reduction in the number of in-patients in the Ear Hospital, mainly accounted for by a smaller number of operation cases for tonsils and adenoids. Congestion of the out-patient department in consequence of the growth of antenatal and child welfare work has necessitated the purchase of several buildings immediately adjoining the Obstetric Hospital. The year's income was £108,000, a slight increase.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY, June 10th.—5 P.M., OPHTHALMOLOGY. Annual General Meeting. Mr. Ernest Clarke : Tay's Choroiditis. LARYNGOLOGY AND OTOLOGY. Summer Meeting at Portsmouth.

SATURDAY.—LARYNGOLOGY AND OTOLOGY. Meeting concluded.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY, 11, Chandos-street, Cavendish-square, W.

THURSDAY, June 9th.—8.30 P.M., Miss Rayner : Individual Psychology in the Children's Clinic.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY, Stepney Green, E.

THURSDAY, June 9th.—3 P.M., Mr. Maurice Sorsby : 1. Demonstration of Cases. 2. Administration of Pre-anæsthetic Medication.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, June 7th, and following THURSDAY.—5 P.M., Dr. J. W. McNee : Liver and Spleen, their Clinical and Pathological Association. (Second and third Croonian lectures.)

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, June 6th.—10 A.M. to 1 P.M., Gynæcological Wards, Genito-Urinary Operations, Skin Department, Surgical Wards. 2 to 4 P.M., Operations, Surgical Wards, Medical, Surgical, Eye, and Gynæcological Out-patients. 4.15 P.M. (Special lecture), Dr. Trevor Davies : Gynæcological Diagnosis.

TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Surgical Demonstration, Throat Operations, Dental Departments. 2 to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Special lecture), Mr. Steadman : Pyorrhœa Alveolaris.

WEDNESDAY.—10 A.M. to 1 P.M., Children's Medical Out-patients, Medical Wards. 2 to 4 P.M., Gynæcological Operations, Medical, Surgical, and Eye Out-patients. 4.45 P.M., Venereal Diseases Demonstration.

THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Fracture Demonstration. 2 to 4 P.M., Operations, Medical, Surgical, Eye, and Genito-Urinary Out-patients. 4.15 P.M. (Special lecture), Mr. Woodd Walker : Subphrenic Abscess.

FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Out-patients, Dental Department. 2 to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Special demonstration), Dr. Archer : Biochemical.

SATURDAY.—9 A.M. to 1 P.M., Throat, Nose, and Ear Operations, Medical Wards, Children's Medical Out-patients, Surgical Wards, Surgical Out-patients. The Lectures at 4.15 P.M. are open to all Medical Practitioners without fee.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 6th, to SATURDAY, June 11th.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-graduate course in Gynæcology, all day.—PRINCE OF WALES'S HOSPITAL, Tottenham, N. Course in medicine, surgery, and the specialties. All day.—CITY OF LONDON HOSPITAL, Victoria Park, E. Course in Diseases of the Chest. All day.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Evening crossing thoroughfares, by marking with a black cross on the street the spots where any pedestrian was killed or severely injured; and whether he would consider the desirability of taking similar action in the Metropolitan police area.—Mr. PYBUS replied: I am aware that action of this kind has been taken by certain authorities abroad, but I doubt whether public opinion in this country would be in favour of it. In any case, I have no statutory power to impose any such obligation on highway authorities.

First-aid Outfits on Motor Vehicles.

Mr. CLARRY asked the Minister of Transport whether he would consider the necessity of requiring all motor vehicles to carry suitable first-aid outfits.—Mr. PYBUS replied: I have already considered this subject. I do not propose for the moment, at any rate, to extend the scope of the existing regulations which requires that these outfits should be carried on public service vehicles which are used as express or contract carriages.

TUESDAY, MAY 31ST.

Safety of Life at Sea.

Mr. HANNON asked the President of the Board of Trade whether, in view of recent serious fires in ships upon the high seas, he would consider the advisability through an international conference of giving effect to the provision embodied in the Convention for Safety of Life at Sea that the materials used in ship construction should be such as to resist the spread of fire and thus prevent loss of life and damage to property.—Mr. RUNCIMAN replied: The International Convention for Safety of Life at Sea, 1929, provides for the fitting of fire-resisting bulkheads, for the establishment of fire patrol and alarm systems, and for the carriage of fire-fighting appliances on passenger steamships, but it does not provide that the materials used in ship construction and fitting generally should be fire-resisting. The question of limiting the use of combustible material in the construction and fitting of passenger ships is engaging the attention of my department in consultation with the shipping industry, and when their investigations are complete the desirability of initiating international action will be considered.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Col. W. R. P. Goodwin, D.S.O., K.H.P., late R.A.M.C., having attained the age for compulsory retirement, is placed on retd. pay.

Lt.-Col. N. E. Dunkerton, D.S.O., from R.A.M.C., to be Col.

Maj. A. C. Hammond Searle to be Lt.-Col.

TERRITORIAL ARMY.

Maj. D. Mackie to be Lt.-Col.

Capt. D. H. Clarke, late R.A.M.C., to be Capt.

Hon. Capt. C. J. L. Wells, late Spec. List, to be Lt., and relinquishes the hon. rank of Capt.

E. M. Wright, late Temp. Lt. R.A.M.C., to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Majs. H. W. Read and S. G. Webb, having attained the age limit, retire and retain their rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE.

Lt. J. H. Crawford to be Capt. (on prob.).

Capt. C. V. Ramchandani relinquishes his temp. commn.

The undermentioned officers retire: Lt.-Col. (Bt. Col.) F. P. Mackie and Lt.-Col. C. H. Barber.

Lt. P. J. Walshe retires on account of ill-health.

ROYAL AIR FORCE.

Flight Lt. D. B. Smith is transferred from Class D (ii) to Class D (i).

Flight Lt. E. J. Mockler relinquishes his commission on appointment to a commission in the Royal Navy.

HONORARY SURGEON TO THE KING.

The King has approved the appointment of Lt.-Col. C. A. Gill, I.M.S., as Hon. Surg. to the King and of promotion to the rank of Brevet-Col.

COLONIAL SERVICE.

Dr. A. Kinghorn, senior medical officer, has been promoted to Deputy Director of Medical Services in Northern Rhodesia, and Dr. C. E. G. Nunns, Medical Officer in Gambia, has been appointed Medical Officer in Nigeria.

MEDICAL NEWS

University of Cambridge.

On May 28th the following degrees were conferred:—

M.D.—J. R. H. Towers.
M.B. and B. Chir.—L. P. J. Evans.
B. Chir.—F. J. Wright.

University of London.

At a meeting of the Senate on May 25th the Dunn exhibitions in anatomy and physiology for 1932 were awarded respectively to Mr. J. E. Spalding and Mr. W. N. Mann, both of Guy's Hospital Medical School.

Dr. A. T. Wilson will give two lectures, on the Physiology of the Adrenal Gland, at the Middlesex Hospital Medical School, Mortimer-street, W., at 5 P.M. on June 13th and 16th. Admission without ticket.

London School of Hygiene and Tropical Medicine.

The next course of lectures in Tropical Hygiene for men and women outside the medical profession proceeding to the tropics, will be given by Lieut.-Colonel G. E. F. Stammers at 5 P.M. on weekdays from June 14th to 23rd. The synopsis may be had from the secretary of the school, Keppel-street, W.C. 1.

Eugenics Society.

At a meeting of this society, to be held at the rooms of the Linnean Society, Burlington House, Piccadilly, W., at 5.30 P.M. on Tuesday, June 14th, Dr. A. S. Paterson will speak on the Law of Anticipation in Mental Disease.

Royal Free Hospital.

On Wednesday next, June 8th, at 3 P.M., the Queen will visit this hospital to open the Queen Mary building (Albert Levy wing) and lay the foundation-stone of the extension of the Alfred Langton home for nurses.

West London Medico-Chirurgical Society.

Sir Thomas Horder will deliver the Cavendish lecture before this society at the Kensington Town Hall at 8.15 P.M. on June 24th. His subject will be the Present Position of Therapeusis in Infective Diseases.

The fiftieth anniversary annual dinner will be held at the Hotel Rembrandt, Brompton-road, on Friday, July 8th, at 7.30 for 8 P.M.

Chadwick Trust.

Weather permitting, an open-air lecture on the Contribution of Plants to the Study of Heredity will be given in the Chelsea Physic Garden, Swan Walk, Chelsea, by Dame Helen Gwynne Vaughan at 5 P.M. on Thursday, June 9th. Sir William Collins will preside, and the gardens will be open at 4 P.M. If it rains the lecture will be given indoors.

Sputum Examinations in Manchester.

The Manchester public health committee have decided to discontinue the payment of fees to practitioners for taking specimens of sputum from patients whom they are attending. It is not intended to discourage the taking of sputum specimens, and the committee feel that cessation of the payments will not deter practitioners from submitting specimens whenever they consider it advisable. The usual fees—namely, 2*s.* 6*d.* for a specimen taken in private practice and 1*s.* for hospital practitioners—will still be paid where specimens are taken at the request of the medical officer of health.

Donations and Bequests.

Mrs. Kate Greatorex, of Mytton Hall, near Shrewsbury, Salop, besides other bequests, left the following legacies: £5000 to the Victoria University of Manchester, and a further £3000 to that University for scholarships for applied and organic chemistry, to be known as "Joseph Travis Scholarships"; £1000 to the Manchester and Salford Hospital for Skin Diseases for endowing a room or bed to be named the "Kate Greatorex" room or bed; £500 to the Manchester and Salford Blind Aid Society; £500 to Shrewsbury Royal Infirmary; £500 to the Oldham Infirmary in memory of Mr. Joseph Travis, and £500 to the Mauldeth Hospitals for Incurables.—Under the will of the late Mr. F. W. Vause the University of Leeds will receive £1000 for the foundation of an entrance scholarship in medicine in memory of the testator's son, who was killed in the war; and a prize in clinical medicine will be established under the will of the late Dr. Hillman, of Wakefield, who left £1000 for that purpose.—Sir John Rutherford, of Blackburn and Roxburgh, formerly M.P. for the Darwen Division of Lancashire, left £2000 for two beds to be named after him, and £3000 to the endowment fund, and his portrait in oils, by Sir William Orpen, to the Blackburn and East Lancashire Royal Infirmary, as well as £1000 to the Blackburn and District Nursing Association.

NOTES, COMMENTS, AND ABSTRACTS

HOMELESS WOMEN.

SINCE the first Cecil House was opened in 1927 ore than 235,000 women and 23,000 babies have een provided with beds for the night, and many ave had to be turned away owing to lack of accom-odation. The Cecil Houses meet, at cost price, e need for clean beds and bathing and washing commodation for homeless and vagrant women. our houses are now in existence, and the premises r a fifth have just been purchased, which. it is oped, will be open before next winter. Funds for e purchase, renovation, and equipment of houses e raised by public appeals, but once they have een established they rapidly become self-supporting. omen seeking lodging pay *1s.* a night, for which ey receive a bed, a hot bath, tea and biscuits at ight, facilities for washing clothes, and tea and read and butter in the morning. This charge is fficient to maintain the premises, cover all costs d pay the salary of the matron and her assistants hose needing beds are asked no questions, and are ot expected to undertake any of the housework; ey are treated as visitors at an hotel, and they ave the satisfaction of feeling that they are paying eir way. A special fund is kept to pay the expenses needy applicants, and no woman is ever turned way because she cannot produce a shilling. Mothers ppreciate the accommodation for children; few dging houses will accept young children, even if e mother can afford to pay for a bed. A case is uoted, in the annual report of the Cecil Houses for 931, of a workman, receiving good wages, who has een unable to find rooms for himself, his wife, and is four children; as a result he and his two sons ve at one lodging house, while his wife and two aughters find beds at a Cecil House.

Attempts are made to avoid the spread of vermin r disease at the houses by a careful daily inspection bed linen. If vermin or traces of disease are iscovered, bed and bedding are sent to a disinfecting tation. During the past year a woman doctor has ade a fortnightly visit to each of the four houses, nd has given free advice to the women lodging there. hrough the coöperation of friends of the movement, mployment has been found for 673 women and girls ho have come to the Cecil Houses when out of work. lthough no questions are asked, confidences are eceived with sympathy, and the matrons make very attempt to find posts for those in search of hem. Mrs. Cecil Chesterton, founder of the Cecil ouses, pointed out in her book—"In Darkest ondon"—that while municipal bodies provide mple sleeping room at reasonable charges for men, t is left for philanthropy and private enterprise to ater for women. Only 16 per cent. of the total icensed sleeping accommodation in the public odging houses of London is available to women, the est being available to men only. It is to remedy his discrepancy that the Cecil Houses are being stablished.

SCIENTIFIC RIDDLES.[1]

A SCIENTIFIC riddle is peculiar in that the answer nly reveals another batch of conundrums, and it as been well said that a discovery is of moment in roportion only as it uncovers fresh problems for olution. In 52 short chapters, Sir Arthur Thomson eals with an immense variety of topics, gives us a reat deal of information, and outlines almost endless ines of inquiry: chromosomes. hormones, partheno-enesis, life in hot places, grey hair, the cuckoo, homing, galls, graft hybrids, telepathy, animal intelligence, evolution, the origin of man: *de omnibus rebus*, in fact *et quibusdam aliis*. The last chapter is headed: Is there purpose in evolution? and is followed by an epilogue on the wonder of the world. This is one of the best of the many good books on biology which Sir Arthur Thomson has written.

DEEP-SEA DIVING.

THE Admiralty Deep Diving Committee of 1907—consisting of Prof. J. S. Haldane, Prof. A. E. Boycott, and Captain G. E. C. Damant, R.N.—found that caisson or compressed air disease is due to too rapid decompression of the diver; the nitrogen which has been dissolved in his body at high pressures escapes as the pressure falls and forms bubbles in the tissues. The committee arranged decompression regulations which made it safe for divers to work for an hour at a depth of 200 ft. That was a great advance, but the necessarily long period of decompression was tedious and exhausting to the diver who, coming up from 200 ft., spent a couple of hours hanging on to a rope in cold, loneliness, and darkness. When diving at even greater depths was called for, this disadvantage had to be faced, and Surgeon Lieut.-Commander A. E. Phillips recently told the United Services Section of the Royal Society of Medicine[1] what has been done to make deeper diving between 200 and 300 ft. practicable and safe. Working at 300 ft. a man is under a pressure of, and breathes air at, ten atmospheres, the partial pressures being for oxygen two, for nitrogen eight. The nitrogen is the difficulty, and to liberate him quickly from it as he ascends he is nowadays given a nitrogen-free atmosphere—i.e., oxygen—to breathe. Decompression has besides been made pleasanter by the invention of the Davis Submersible Decompression Chamber (Siebe, Gorman and Co.). This is a steel chamber, lowered like a diving bell, into which the ascending diver makes his way, and there, when the hatch is closed, he finds himself in a lighted chamber with one or two attendants who give him an oxygen-breathing apparatus and hot coffee. Sitting there he can play cards or otherwise pass the time of his decompression, which is now shortened by a half or a third. Thus he can spend more time at work and get more done. The work needs a strong man, but is not exhausting, and the diver is definitely refreshed by breathing the oxygen supplied. "One of our divers reached 344 ft. and came to the surface as one might return from an afternoon's walk." No case of oxygen poisoning has occurred; lung fibroses have in every case diminished, and some functional albuminurias have improved. The rubber suit is more useful than the rigid all-metal outfit for rapid work, necessary, for example, when saving lives from a disabled submarine. Lieut.-Commander Phillips gives complete directions for choosing divers, who must be strong men without medical defect, steady, and self-reliant; it is not now thought important to refuse men who are moderately stout.

IS THERE A MALARIAL PNEUMONIA?

WORKING at the Institute for Tropical Medicine at Hamburg, Dr. M. Salah Eldin has endeavoured to answer the question whether malaria can produce definite lesions in the lung. In his paper,[2] written in English, he discusses the post-mortem appearances of eleven cases seen at Hamburg, two of inoculated malaria, nine of unselected chronic subtertian (named in Germany "tropical"). Of these, four were histologically pneumonia, and pneumococci were seen in two. In the other seven the condition was not a fibrinous exudative inflammation, but a congestive proliferative lesion of the alveolar wall; the capillaries were dilated and congested with swelling of their endothelium, and swelling and proliferation of the alveolar epithelium; in one case there were minute multiple infarcts. Malarial pigment was seen, in these cases, in mononuclears in the distended capillaries and in their endothelium: in one case a few were found in the alveoli. Eldin thinks that pneumonia can only with difficulty be differentiated from massive collapse, encouraged perhaps by

Appointments

BOWER, M. DYKES, B.Ch. Oxf., D.O.M.S., has been appointed Honorary Assistant Surgeon, West of England Eye Infirmary, Exeter.

JONES, GWYN R., M.B., B.Chir. Camb., County Pathologist and Bacteriologist, Monmouthshire.

MILNE, Isabella A., M.B., Ch.B. Glasg., Asst. Medical Officer of Health, Blackpool.

ROBINSON, Miss M., M.B., B.Ch., B.A.O. Belf., District Resident Medical Officer, Queen Charlotte's Maternity Hospital.

Vacancies

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Diseases, Austral-street, West-sq .S. At rate of £100.
Altrincham un. H.S. At rate of £150 an
Barrow-in-F *'al.*—H.S. £175.
Basingstoke, —Second Asst. M.O. £450. Also Jun. Asst. M.O. £350.
Bedford County Hospital.—Second H.S. At rate of £140.
Birmingham Children's Hospital.—Res. Surg. O. £175.
Birmingham City Mental Hospital.—Jun. Asst. M.O. £350.
Birmingham and Midland Eye Hospital, Church-street.—H.S. £110.
Bradford Royal Infirmary.—H.P. and H.S. Each at rate of £135.
Brighton County Borough, Public Assistance Committee, Poor-law Institution.—Res. M.O. £850 and Sen. Res. Asst. M.O. £400.
Burnley, Victoria Hospital.—H.P. At rate of £150.
Burton-on-Trent, Bretby Hall Orthopædic Hospital.—Locum. At rate of £350.
Bury and District Joint Hospital Board.—Asst. to Med. Supt. £400.
Bury Infirmary, Lancs.—Third H.S. At rate of £150.
Canterbury, Kent and Canterbury Hospital.—H.S. At rate of £125.
Cardiff, City Lodge Institution.—Asst. M.O. £150.
Carlisle, Cumberland Infirmary.—Second H.S. £155.
Carmarthen, Joint Counties Mental Hospital.—Laboratory Asst. £150.
sing Assoc.—Asst. Supt. £90.
—H.S. and H.P. Each at rate of £150.
, 7, *Buckingham Palace-gardens, S.W.*—
Psychiatry. Each £150.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Colchester, Essex County Hospital.—Asst. H.S. £120.
Dewsbury and District General Infirmary.—Second H.S. £150.
Doncaster Royal Infirmary.—Cas. H.S. At rate of £175.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.
Durham County Council Education Department.—Asst. Oculist. £500.
East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £200.
East *en, Shadwell, E.*—H.P. and H.S.
Eveli *ildren, Southwark, S.E.*—Hon.
Exeter, Royal Devon and Exeter Hospital.—Sen. and Jun. H.S. At rate of £250 and £150 respectively.
Freemasc *Home, 237, Fulham-road, Chel* ite of £250.
Fulham *Hammersmith, W.*—Clin. Asst. At rate of £100.
Halifax, St. Luke's Hospital.—Jun. Res. M.O. £250.
Hammersmith Hospital, Ducane-road, Shepherd's Bush, W.—Res. Asst. M.O. £350.
Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.S. At rate of £100.
Hôpital and Dispensaire Français, 172, Shaftesbury-avenue, W.C. Jun. Res. M.O. £100.
Hull Royal Infirmary.—Third H.S. At rate of £150.
Indian Medical Service.—Appointments Commission.
Lincoln County Hospital.—Jun. H.S. At rate of £150.
Liverpool Hospital for Consumption and Diseases of Chest.—Asst. M.O. and Pathologist. £150.
London University.—Laura de Saliceto Studentship. £150. Also Examinerships.
Middlesbrough, North Ormesby Hospital.—H.P. £120.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E. Assist. Cas. O. At rate of £125.
Miller General Hospit Cas. O. At rate of £150. Also tw at rate of £100.
National Hospital, st. Pathologist. £250.
Newcastle General Hospital.—H.S. At rate of £150.
Northampton General Hospital.—H.S. At rate of £150.
Nottingham General Hospital.—Res. Cas. O., also H.S. At rate of £200 and £150 respectively.
Paddington Green, Children's Hospital, W.—H.P. and H.S. Each at rate of £150.
Plymouth, Central Hospital.—Res. H.S. At rate of £150.
Preston, Lancs, Biddulph Grange Orthopædic Hospital.—Jun. H.S. £150.
Royal Free Hospital, Gray's Inn-road, W.C.—Asst. Phys.
Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.
St. George-in-the-East Hospital, Raine-street, Wapping, E.—Res. Asst. M.O. £350.
St. Mary's Hospital for Women and Children, Plaistow, E.—Two Hon. Asst. Phys. Also Clin. Asst. for Med. Outpatients' Dept.
St. Mary's Hospital, W.—First Asst. Pathologist. £500.
St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C. Clin. Assts.
Salford.—Asst. Res. M.O. for Hope Hospital, Pendleton. At rate of £250.
Salford Royal Hospital.—Med. Reg. £250. Also H.P.'s and H.S.'s. Each at rate of £125.
Salisbury General Infirmary.—Two H.S.'s. Each £150.
Sheffield City.—Asst. Tuberculosis O. £350.
Sheffield, Jessop Hospital for Women.—H.S. At rate of £120.
Southampton, Royal South Hants and Southampton Hospital.—Radium Officer. £600. Also H.P., 2 H.S.'s, and Cas. O. Each at rate of £150.
South Shields, Harton Hospital.—H.S. £150.
Warrington Infirmary and Dispensary.—Jun. H.S. £175.
Warwick, King Edward VII. Memorial Sanatorium, Hertford Hill.—Jun. M.O. At rate of £200.
West End Hospital for Nervous Diseases, Regent's Park, N.W.—Jun. H.P. At rate of £100.
West London Hospital, Hammersmith-road. W.—H.P. and H.S. Each at rate of £100.
66, Fitzjohn's-avenue, Hampstead.
Sanctuary, S.W.—H.S. to Eye and Ear, Nose and Throat Depts. At rate of £102.
Weston-super-Mare General Hospital.—Res. H.S. £150.
Windsor, King Edward VII. Hospital.—Two H.S.'s. Each at rate of £100.
Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. and H.S. Each at rate of £100.
Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £150.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Romford (Essex); Slaithwaite (York, West Riding); Huddersfield, West (West Riding); Lenham (Kent); and at Broughton (Hampshire).

Births, Marriages, and Deaths

BIRTHS.

JAUCH.—On May 27th, at Grantham, the wife of F. J. Jauch, F.R.C.S., of a son.

NICHOLSON.—On May 22nd, at Park-road, West Hartlepool, the wife of Dr. W. A. Nicholson, of a son.

SIMONS.—On May 20th, at Plymouth, the wife of Major G. E. L. Simons, R.A.M.C., of a son.

MARRIAGES.

SEARS—GOULD.—On May 28th, at Thornton Heath Wesleyan Methodist Church, W., Gordon Sears, M.D., M.R.C.P., to Eileen Gould.

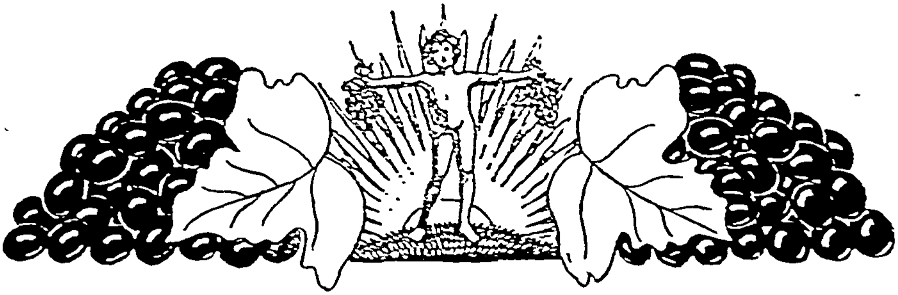
DEATHS.

FAWSITT.—On May 26th, at his residence, "Holmfield House," Oldham, Thomas Fawsitt, M.R.C.S., L.R.C.P., in his 87th year.

McCALMAN.—On May 18th, at the Chaplain's House, Welbeck, Worksop, Notts, Lieut.-Col. Hugh McCalman, M.D., I.M.S. (retired), aged 82 years.

WATNEY.—On May 28th, at Buckhold, Pangbourne, Herbert Watney, M.D., F.R.C.P. Lond., aged 89.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.



IS INCOMPLETE EVACUATION A SOURCE OF DANGER ?

It is authoritatively stated that " completeness of evacuation is even more important than regularity of evacuation." Many people who report a daily bowel movement yet manifest and experience the symptoms and discomfort characteristic of constipation. Laymen are not always good judges of adequacy in this matter.

If this partial retention of waste is allowed to continue uncorrected, an atonic habit is created, and the constipation tends to become aggravated. In such cases, ENO's " Fruit Salt " has been found of great value, being mild and unirritating, though effective, in its stimulant action on peristalsis. It may safely be taken, even over long periods of time, without injury to the mucous lining of the bowels or to the sensitiveness of the nerve-endings. ENO is entirely free from the harsh mineral sulphates, Epsom and Glauber salts. It is agreeable and refreshing to the palate ; and is found by many strikingly to promote a feeling of fitness and general well-being.

ENO'S "FRUIT SALT"

J. C. ENO LTD., 160 PICCADILLY, LONDON, W.1 malarial splenitis; the lessening of this during the remission would explain the intermittent nature of the symptoms. He concludes that true pneumonia in a case of malaria is due to an additional infection. The malarial parasite cannot produce in the lung a fibrinous exudative inflammation, but a lung with malarial lesions (proliferative congestion of alveolar walls) is liable to secondary infections. Malaria attacking the lung leads to congestion and œdema or to massive collapse, usually mistaken for pneumonia. He adds that pneumonia is not due to malaria, and he quotes, apparently with approval, the opinions of authors who argue that malaria does not prepare the way for tuberculosis.

PROFESSIONAL SIDELIGHTS.

FOUR small books, three English and one American, have reached us dealing with the attitude, professional and social, that the doctor should adopt towards his patient and the public.

Bedside Manners. By CHRISTOPHER HOWARD, M.R.C.S., L.R.C.P. London: John Bale, Sons and Danielsson, Ltd. 1932. Pp. 104. 3s. 6d.—Having read Mr. Howard's "After Consulting Hours," we anticipated with pleasure the perusal of this little volume. We were not disappointed. Mr. Howard writes with an agreeable air of broadmindedness, of humour, and of shrewdness, and although some of his opinions here expressed will arouse controversy, even those who are in opposition will enjoy his pages. We cannot imagine many surgeons failing to be stirred to denial by his demonstration of the discrepancy in their favour between the fees of surgeons and of physicians. Nevertheless, we believe he is right in the main. Those who want to be able to say what they mean by a bedside manner will find an amusing and just account in the first chapter, and those who want a sensible view of the constituents of real success will meet it later on. Mr. Howard is amusing but not flippant, and he shows a sincere appreciation of the true value of the genuine practitioner, just as he does an admirably expressed depreciation of him whose shop window is impressive but whose stock-in-trade is scant. He has wise observations on punctuality and the latest methods, and foreign study and specialisation, and there must be few medical men who will not thoroughly enjoy their hour with this little book.

A Guide to General Practice. By A. H. DOUTHWAITE, M.D., F.R.C.P. Lond., Assistant Physician to Guy's Hospital. London: H. K. Lewis and Co., Ltd. Pp 96. 4s. 6d.—Dr. Douthwaite's little book has a large scope and deserves its important title. In the first place the advice to those entering general practice and on the business aspect of the general practitioner's life, is exactly the sort that senior students and young doctors require—it is, in the author's words, a "recognition that a dangerous hiatus exists between the intensive hospital education of the medical student and the hard won self-education of the experienced medical practitioner." The methods of choosing and entering a partnership are illustrated by the inclusion of a typical partnership agreement of a complicated sort. It is an agreement entered into by an incoming partner (X) replacing one who is retiring (B), and joining three partners of whom (A) and (S) have equal shares, and (T) a smaller part. (X) is unable to pay the full purchase price on entry. It is a good mental exercise to follow the clauses of this agreement and see how fair interplay was secured between (A), (S), (T), and (X). The advice given on the conduct of general practice, with which the book closes, is sound.

The Surgeon. By C. JENNINGS MARSHALL, M.D., M.S. London: Geoffrey Bles. Pp. 192. 3s. 6d.—This is the latest volume of the Life and Work Series, and inside its small compass a fair general picture is given of the surgical profession in England to-day. There is wise counsel to the student on the qualities which he should cultivate before qualification, and the chapters which follow on the risks of operations, and on their performance and after-treatment resume generally held views in a pithy manner. The chapter entitled "The Need for Operation" is full of good sense, the well-known difficulty of deciding between the various arguments that make for and against surgical interference being well set out.

The Young Doctor Thinks Out Loud. By JULIAN PRICE, M.D. London: Appleton and Co. Pp. 187. 5s.—Dr. Price points out that the working hours of the medical student between 18 and 28 are so crammed with the collection and application of information that he has little time to do original thinking, and he proposes to think for him. The result is a series of chapters dealing with the choice of medicine as a profession, with the preliminary and technical education necessary, with the value of holding of appointments, with the experiences of an entrance into general practice, and with the decision to become a specialist. Here we have set out briefly professional ideals and performances in the United States, and the close similarity with which analogous positions are regarded on each side of the Atlantic shows once again how international a thing sound medicine must be.

THE FEAR OF A HIGH BLOOD PRESSURE.

THANKS to the publicity given to the condition of blood pressure in the popular press there are at this time a large section of people whose lives are a constant burden to them because they have at some time or another been told they are suffering from a high blood pressure. Dr. C. L. Andrews has written a book[1] in a style that any layman can understand, expressly for these unfortunates who, to quote his own words, "are the victims of blood-pressure psychology, and who because of hearsay, misinformation, and inability to separate cause from effect live in constant fear of some impending body calamity which may never occur, so far as blood pressure is concerned." There are those who will consider that such a book will tend to make the person who reads it more introspective as regards his health. By making it possible for any layman to get an intimate knowledge of this one disease it may help to exaggerate its importance rather than, as is hoped, to lay its ghost. But before condemning the book on these grounds it should be remembered that the unknown always hold more terrors than the familiar, and that knowledge should dispel superstition.

The book is very readable, and should be easily understood by anyone with average intelligence. The first two chapters explain the meaning of blood pressure and its relation to the circulation of the blood. Then follows an explanation of how blood pressure is estimated, and what is the normal reading at various ages. This is followed by two chapters dealing with high and low pressure respectively, the subject being made more easily understood by an analogy with the motor-car. The last part of the book is devoted to causes of high and low pressure, and their relation to the facts and functions of daily life. The author states that if he has convinced his readers that blood pressure itself is not a disease his mission will be fulfilled.

A REFERENCE LIBRARY FOR MIDWIVES.

THE honorary librarian of the Midwives' Institute writes to ask any medical man who is giving up practice or weeding out his library, to bestow upon the institute any medical works—especially textbooks on gynæcology, obstetrics, anatomy, hygiene, or public health—that he no longer requires. The institute would gladly defray the cost of packing and transit. A reference library of about 900 volumes has already been built up with the help of books from friends in the medical profession. The address of the Midwives' Institute is 12, Buckingham-street, Strand, W.C.2.

Triumphant Motherhood

IN the past the choice of an artificial food, when for any reason an infant could not be breast-fed, imposed a heavy responsibility upon the physician. In recent years, the increasing range of Cow & Gate Milk Foods designed to meet any aspect of infant feeding no matter how difficult, has done much to lighten this burden.

This picture of a happy mother and a healthy, intelligent child is typical of the results which the profession are achieving all over the world with this remarkable substitute for natural milk.

Clinical samples and literature of the whole range of Cow & Gate Products will gladly be sent on request.

First Prize winner of the News Chronicle "Mother and Child Beauty Competition," 1932.

TESTOGAN

(Masculin) Ampoules and Tablets.

In cases of sexual disharmony, impotence, sexual weakness, climacteric troubles, etc.

THELYGAN

(Feminin) Ampoules and Tablets.

Infantile sterility, sexual disturbances in obesity, and other metabolic disorders.

Climacteric symptoms, amenorrhœa, neurasthenia.

LIPOLYSIN in OBESITY

(Male and Female) In tablets and ampoules.
(DR. HENNING)

Pluriglandular, Antilipogenetic.

BISMOLAN

Suppositories and Lubricant.

In the treatment of Hemorrhoids Bismolan preparations are antiseptic, prevent the passage of infectious germs into the veins, contract the mucosa and blood vessels, cause the hemorrhoids to diminish in size, thereby avoiding the danger of bleeding.

Bismolan Suppositories are indicated to all inflammatory conditions of the proctologic area.

ATOCIN

In 7½ grain tablets. Also with Aspirin (5 grains Atocin, 2½ grains Aspirin).

RHEUMATISM, GOUT, LUMBAGO, NEURALGIC, and SCIATIC CONDITIONS.

Unsurpassed for pain-relieving qualities and as a uric acid eliminant.

Extensive Literature and Case Reports on request.

CAVENDISH CHEMICAL CO. (New York), LTD.,
137, REGENT STREET, LONDON, W. 1.

When the buffer bodies are depleted

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

as in acidosis, acidemia and their correlated pathological disturbances, rational alkaline medication is essential.

Alka-Zane containing alkaline salts in proportions adapted to the physiological requirements of the body, promptly corrects hyperacidity, promotes diuresis and the restoration of the all-important alkaline reserve.

A trial will demonstrate the outstanding merits of

ALKA-ZANE

Literature and samples to physicians on request.

ADDRESSES AND ORIGINAL ARTICLES

THE OBSTETRIC FORCEPS AND ITS USE*

MABEL DOBBIN CRAWFORD, M.D., M.A.O. DUB.,
F.R.C.S. IREL.,

HON. ASSISTANT SURGEON TO THE LIVERPOOL AND
SAMARITAN HOSPITAL FOR WOMEN, AND TO THE
LIVERPOOL MATERNITY HOSPITAL.

his communication is a result of my experiences he Liverpool Maternity Hospital during one week.

was called to an emergency—a failed forceps . I found a patient with contracted pelvis and ost-mature fœtus: no chance of delivery by ral means. The maternal trauma was slight, fœtal heart good. I delivered by Cæsarean on, only to find that the baby had bled copiously one ear, there being a stellate fracture of the etal and sphenoidal region of the skull. Although heart continued to beat for a few moments, the d never breathed.

few nights later my maid brought me the very message that I was wanted at once at hospital another of those failed force” cases. Two ors had brought a woman by ambulance and me the following history.

> e patient was a primigravida, aged 42. After 20 hours e first stage of labour the senior practitioner considered had suffered long enough and put on forceps. His strength failed to deliver her, and he summoned a colleague to try the power of his younger muscle. also failed. Hæmorrhage began, a constant trickle. called an ambulance and brought the woman into al, a distance of some 14 miles, bleeding continually whole way.

und her blanched and still bleeding, with a ady pulse and pulse-rate of 140. The cervix only three-quarters dilated and torn in three es; one tear, the length of my finger, extended the left fornix, and there was also a deep lacera- in each side of the vagina. The vertex was enting, free above the brim, the fœtus post- ure, and the pelvis contracted, the diagonal ugate being less than 4. A craniotomy saved mother, but there was no reason why, with ante- l care, a Cæsarean section should not have d the infant too—a desirable result in a primi- ida of 42 years of age.

thereupon decided to investigate these cases.

Proper Use of Forceps

he obstetric forceps—applied when the signs are urable—is an instrument of mercy. It is easy se, and by its aid a woman may be saved much ring. Yet eminent obstetricians have seriously tioned whether women would not be better off this instrument never been invented. For in itable cases or at an improper time the forceps lethal weapon whereby thousands of living ies have been killed and scores of mothers ght to the door of death. Because this instru- is so perfectly adapted to the proper case, vering a woman so readily and without injury nother or child, it always conveys the impression useful tool, assuming an appearance of innocence ote from its true character.

he art of obstetrics is practised more by rule-of- mb than any other branch of medicine, it being inevitable that a science which has grown steadily through the centuries should impose upon its practitioners certain rules which cannot be violated with impunity. The obstetrician, then, needs only to make an accurate diagnosis and his course lies clear before him. The rules for the application of forceps are four.

1. Forceps may only be applied during the second stage of labour—that is, when the cervix is fully dilated and taken up. I find a common misconception on this point. Our house surgeons will sometimes write upon a case sheet: patient in second stage, cervix fully dilated—*anterior lip œdematous*. This, of course, is nonsense. The cervix is not fully dilated if a lip can be felt anywhere. Moreover, if a small rim can be felt anteriorly there will almost certainly be a larger rim present behind.

In rare instances, where every other condition is favourable and delivery urgent, it may be permissible to incise a thin margin of cervix, but it is never justifiable to drag a fœtus through a partially dilated os; the resulting lacerations may cause the mother's death or turn her into a chronic invalid.

2. The second rule is that the head must be fixed and the largest presenting diameter must have passed through the pelvic brim. The forceps, ideally, is an instrument for lifting the fœtal head over the perineum. It may be applied on occasion to the head in the middle strait—that is fixed, the largest diameter through the brim but not yet descended to the perineum. The application of forceps to a head above the brim is absolutely unjustifiable: the instrument so used is a compressor, whereas its proper function is that of traction only.

The application of forceps is only a success—as stated by Berkeley—when their use leaves the mother no worse off than she was before their application, and when the child is born alive. If the maternal efforts fail to mould the fœtal head through the pelvic brim, then the dragging-through of that head by means of forceps is as certain to kill the child as a craniotomy, and far more liable to injure the mother. Choice must rest between correction of malpresentation, Cæsarean section, or craniotomy—or, perhaps, pubiotomy.

3. The presentation must be favourable, vertex with the occiput anterior. Occasionally the use of forceps is permissible in face presentation where the chin is to the front; in brow, where the whole head has passed into a roomy pelvis; or, rarely, in a vertex presentation with the occiput posterior.

4. The membranes must have been ruptured.

An Analysis of 100 Cases

In order to demonstrate the frequency of the abuse of this beautiful instrument and to illustrate the results of forceps applied in unsuitable cases, or at a wrong time, I have analysed the histories of the last 100 patients who were sent into the Maternity Hospital as emergencies, after attempts at delivery by forceps had failed. Five of these cases had been attended by our own house surgeon on the district; the remaining 95 were sent in by doctors in private practice. I am much indebted to my colleagues at the Maternity Hospital for permission to investigate their cases with my own. They occurred during a period of seven years.

Antenatal Care.—In no case had the mother attended an antenatal clinic in the hospital; twelve women had attended outside clinics, four had ceased

---

A paper read before the Liverpool Medical Institution.

attendance early, and one had been advised to come into hospital for confinement but had refused.

Parity.—As to parity, 42 were primigravidæ and 58 multigravidæ. If dystocia occur in the first labour one is more anxious as to the shape and size of the pelvis, while in the multigravida anxiety is concentrated upon the size of the fœtus and the condition of the uterine muscle. The multiparous uterus is more likely to rupture in the presence of any obstruction to delivery. One woman was in her twentieth pregnancy, two in their fifteenth, one in her fourteenth, one in her twelfth, three in their tenth, and five in their ninth pregnancies.

REASONS FOR APPLICATION OF FORCEPS.

The reasons given for forceps delivery are set out in Table I.

TABLE I.

(*A*)	None			20
(*B*)	Disproportion—			
	Post-maturity	54		
	Occipito-posterior	29	58	
	Contracted pelvis	22		64
	Hydrocephaly		3	
	Brow		3	
(*C*)	Prolapse of cord			5
(*D*)	Face presentation			9
(*E*)	Impacted breech			1
(*F*)	No note, born before admission			1
				100

(*A*) In 20 cases there was no discoverable reason why forceps had been applied. About half of these had a slow first stage, but that is no indication for forceps. One case showed a remarkable error in diagnosis.

The woman was having twins; one child having arrived there was a little delay, and the midwife sent for a doctor. He came, put on forceps which slipped off repeatedly, and sent the woman into hospital. On admission she was found to have the second amniotic sac intact, the head ballotting freely above the brim, so that forceps must have been applied outside unruptured membranes. All this patient needed was a puncture of the membranes, whereupon she delivered herself with ease.

(*B*) There were three main factors in *disproportion*—namely, post-maturity, occipito-posterior position, and contracted pelvis. In three cases the disproportion was due to hydrocephaly, and in three cases to brow presentation.

Post-maturity.—Of the 100 mothers, on admission four were premature, 42 at term, and 54 were post-mature. It may be a very serious thing for a woman to go past her time. Not only does the fœtal head increase in size, but there is a marked increase in calcification. In one of the cases in my series 44 weeks had elapsed since the last menstrual period, and during the post-mortem examination of the infant the calvarium could only be removed by means of a saw. The post-mature fœtal skull permits of very little moulding. With the varied means at our disposal for the induction of labour at term, no woman need run this risk of difficult labour if she consults a doctor during her pregnancy. The prevention of post-maturity alone would justify antenatal supervision.

Occipito-posterior position (29 cases).—In a vertex presentation, a posterior position of the occiput is always accompanied by incomplete flexion of the head—that is to say, the lowest part of the head is not actually the vertex, but rather the anterior fontanelle, or some part between the anterior fontanelle and the vertex proper. Were the head well flexed and the vertex advanced the latter would be turned forwards by the action of the muscles of the pelvic floor. This incomplete flexion may be the cause of dystocia, for the engaging diameter is the fronto-occipital, averaging 4½ inches, instead of the suboccipito-bregmatic, which averages but 3¾ inches.

Given sufficient time, most cases of occipito-posterior position will result in spontaneous rotation and delivery, failure occurring where the uterine contractions are feeble, or where the pelvic floor has been damaged in previous confinements. The proper treatment of a posterior position of the vertex may be undertaken during the last weeks of pregnancy. Before labour starts the patient should lie upon her other side during her hours of rest. Very commonly the back of the fœtus and the occiput will rotate to the front, as a result of this postural treatment alone. It is so successful that we very seldom employ the pad and binder method of Buist, which, although it has many successes to its credit, is a very uncomfortable procedure for the patient. I have seen at least one case where the fœtus was made so unhappy that it turned from a vertex presentation to a breech.

During labour, and after the head has fixed, the patient should lie on the same side as the occiput, that gravity may favour its descent and rotation. Plenty of time should be allowed. It may be wise to leave the patient for several hours in the second stage, giving sedatives for uterine inertia, that vigour may be renewed after a rest. I do not think it can be sufficiently emphasised that obstetrics cannot be done by the clock. Signs of fœtal or maternal distress are an indication to complete delivery, not the duration of labour. If signs of distress appear, the head should be rotated manually, one hand in the vagina grasping the occiput and coaxing it round while the fœtal body is rotated in the same direction. Manual rotation may be followed by spontaneous or by forceps delivery.

Very rarely forceps may be applied to a head in the occipito-posterior position. The head will usually rotate as it descends, when the forceps may be taken off and reapplied.

Of these 29 cases all but seven were complicated by post-maturity or contracted pelvis or both. Delivery was effected in hospital as follows: in 8 cases by sedatives (spontaneous rotation and delivery); in 6 by manual rotation and forceps delivery; in 5 by forceps delivery, the head rotating during the operation in 2 cases; in 3 by Cæsarean section; and in 7 by craniotomy; 14 infants died or were stillborn; 4 mothers died.

The *pelvis was contracted* in 22 cases, the contraction in nearly all being of minor degree, the diagonal conjugate measuring from 4 to 4½ inches. In this minor degree of pelvic contraction a normal head will very commonly mould through the brim if the fœtus be not post-mature. Progress will be aided by placing the mother in Walcher's position during the second stage. If there be disproportion, and if, with the progress of labour, the head is not moulded through the brim, forceps must not be used, for under these circumstances it is only an instrument of trauma.

Pelvic contraction should be discovered during pregnancy. The best time to examine the pelvis is between the thirtieth and thirty-sixth weeks. Earlier, the maternal parts may not have softened sufficiently to allow palpation of the sacrum, while after the thirty-sixth week the fœtal head is usually in the way, although it may rise above the brim again as it grows larger. In a normal pelvis the sacral promontory is out of reach when examination is made by two fingers. If there is any doubt in the case of a primigravida, it is wise to examine the pelvis under ether with the half hand in the vagina. This is much better done a week or two before term in order to avoid manipulation during labour.

t cannot too often be repeated that contraction :he pelvis is not an indication for the use of forceps.

a recent congress of British obstetricians and næcologists, when minor degrees of pelvic con-ction were under consideration, speakers con-tulated one another that no mention had been de of forceps as a remedy.

C) *Prolapse of Cord.*—In five cases forceps were d because the cord had prolapsed, with a vertex sentation—*presumably an attempt to rescue the* perilled fœtus. In one case, after admission to pital, the cervix only admitted two fingers; the ceps must have been applied outside the cervix. ree of the five infants were stillborn or died. The atment of prolapse of the cord is sometimes very icult, but if the woman be placed in the knee-st position the cord can often be persuaded to up above the presenting part and a tight binder y prevent recurrence. In one case the doctor l very skilfully replaced the cord but, not content h this, had applied forceps three times through a rter-dilated cervix, killing the fœtus and lacerating mother. Once the cord has been replaced there no hurry. Forceps are only indicated when all ditions for their application are fulfilled.

D) There were nine cases of face presentation. ree of these were post-mature, and in three the d had prolapsed during manipulations. In two es, on admission, the leg was found prolapsed ide the head, the result of an attempt at sion. All nine infants were stillborn, and one ther died. Face presentation is not at all favourable, provided the chin is directed forwards turns to the front. The engaging diameter is ial to that in a vertex presentation, averaging inches.

Considerable time must be allowed in the second ge of labour. If the pains are deficient, rest should given by morphia or chloral. It does not matter w many hours are spent so long as the mother is ting and the fœtal heart keeps good. If signs of tress appear, the head should be rotated manually, l may then be born naturally or extracted by ceps. If the head be impacted with the chin sterior, the fœtus will be dead and labour should terminated by craniotomy.

E) The case of *impacted breech* will be mentioned ongst the maternal deaths.

COMMENT ON THESE REASONS.

Considering, now, the rules for the application of ceps, we find that the required conditions were sent in only 4 of the 100 cases. In 52 cases forceps re contra-indicated; in 44 they had been applied soon.

Take the first rule: in 59 cases the woman on mission to hospital was in the first stage of labour, smallest degree of cervical dilatation being a o-finger os. In these 59 cases severe maternal erations were present in 40, the cervix, vagina, d perineum being extensively torn. In one case ceps had so torn the undilated cervix that a large gment of the posterior lip was hanging outside the lva, attached to the uterus by a narrow strip of sue; this woman lived, but was invalided by a lvic cellulitis.

In three cases the uterus was ruptured. In one e child had been born, but the placenta was in the dominal cavity; in the other two the fœtus had rtially escaped through the rent. All three others died. Permanent fistulæ into bladder, ctum, or urethra developed in four cases.

Casual examination will frequently fail to detect the thinned-out cervix of a primigravida.

A friend of mine, called to lend a hand in a difficult confinement, discovered his colleague vastly puzzled *because he could not deliver the woman by forceps,* failing to notice that at each pull not only the fœtal head, but also the cervix showing a half-inch external os, was presenting at the vulva, the forceps being applied to the vaginal vault.

With regard to the second rule, we find that of the 100 cases the head was free above the brim on admission in 36, forceps being therefore contra-indicated. In 34 the head was entering, the largest diameter being still above the brim; the forceps had therefore been put on too soon.

In 27 this condition was fulfilled, the head being fixed in the pelvis. In two the child had been born, and in one the breech was presenting.

It is a good working rule that, if forceps applied once fail to deliver, the diagnosis is at fault. There is no point in repeating the error. Rather should the diagnosis be corrected by examination with the half or whole hand in the vagina while the patient is still asleep. In many of the cases in my series there is no record of this point; it is, however, stated that forceps had been applied once only in eight cases, twice in nine cases, three times in four cases, four times in one case, five times without an anæsthetic in two cases, six times in one case, and several times in four cases. In one case the forceps had been on for two hours, and in one for three hours.

Whatever may be one's opinion concerning anæsthetics in midwifery, the day is surely past when, in a city practice, operation without anæsthetic can be justified. Any doctor who, having a parturient woman at his mercy, puts on forceps without an anæsthetic, and, failing to deliver, repeats the procedure four times, is, in my opinion, deserving of very severe censure. One of these women, we were told, awakened the neighbourhood with her screams, and she quite certainly died within 16 hours of her admission to hospital.

RESULTS OF THE MISAPPLICATION OF FORCEPS.

Table II. shows the results of the misapplication of forceps.

Of the twelve mothers who died, five died from sepsis, six from shock, one from paralytic ileus on the fifth day after Cæsarean section. Three were primigravidæ. Of the five mothers who died from sepsis :—

One died on the seventh day after Cæsarean section.

Two died after craniotomy of septicæmia and pelvic cellulitis. One of these was in her ninth pregnancy, the whole trouble being that she was post-mature.

One died a few hours after admission, mother and child showing gross infection with a gas-forming bacillus. This was the primigravida who had had forceps applied five times without an anæsthetic.

The fifth was admitted collapsed, forceps having failed; the fœtus had been turned to a breech and extracted as far as its neck before admission. After craniotomy, the infant weighed 11 lb. The mother had already had seven normal labours.

Of the six mothers who died from shock and hæmorrhage, four died undelivered.

In one, we were told, the fœtus had presented by the brow. Forceps were applied after manual flexion of the head to a vertex and failed. Pituitrin was given twice, and version attempted. The woman arrived in hospital with a pulse-rate of 170, the fœtal head presenting above the pelvic brim, and prolapsed beside it were both arms, one leg, and a loop of cord.

The second was a case of impacted breech. Delivery having been attempted by forceps and by a blunt hook, varicose veins in the vagina and vulva were ruptured and death followed from hæmorrhage, a large hæmatoma forming in the pelvic cellular tissue.

In the third case, the cause of the trouble was post-maturity and occipito-posterior position of the vertex. The mother was shocked on admission to hospital, collapsed during a craniotomy, and died.

In the fourth case the uterus had ruptured while the doctor was trying to extract the second of twins, and the mother was moribund on admission to hospital. This was her ninth labour, the previous eight having been normal.

The fifth mother died immediately after hysterectomy for ruptured uterus, while the sixth to die of shock arrived in hospital collapsed, forceps having been applied during the first stage of labour to a head free above the brim; a torn rim of cervix was still present, and the vagina was torn into the urethra in front with an extensive tear in the posterior wall. The mother was treated for shock and delivered by craniotomy, but died almost immediately. She had previously had five normal labours.

Twenty mothers, treated by sedatives and given rest, were delivered spontaneously, but only eleven of their infants survived. Of the 62 infants who died or were stillborn, three only were macerated at birth. In each of these cases labour had continued for over 60 hours, therefore possibly the fœtus had been alive at the onset of labour. The remaining 59 infants were presumably alive at the onset of labour. Of the 62 infants, 28 were born by craniotomy. The causes of death in the remaining 34 were as follows (Table III.) :—

TABLE III.

Cranial injury—	
[illegible]	6
racranial hæmorrhage	7
[illegible]	1
dying undelivered	4
Prolapse of cord	5
No abnormality found and no post-mortem examination	9
True knot in cord round neck	1
Infection by gas-forming bacillus	1

Nine of the infants who survived sustained birth injuries—two having depressed fractures of the parietal bone and four having cephalhæmatoma.

TABLE IV.—*Failed Forceps Cases.*

		Averages for the Maternity Hospital for the past five years.
Maternal mortality	12 per cent.	1·25 per cent.
,, *morbidity*	31 ,, ,,	6·42 ,, ,,
Fœtal mortality	62 ,, ,,	11·2 ,, ,,

Table IV. shows the mortality and morbidity of the cases in which forceps delivery failed.

If we separate these into booked cases who have attended our *antenatal clinic* and emergencies wh have not, we *get the following* figures :—

	Booked cases.	Emergencies.
Maternal mortality	0·53 *per cent.*	3·92 per cent.
,, morbidity	4·76 ,, ,,	15·0 ,, ,,

I submit that the abuse of forceps, with its tra results, can be avoided by :—

1. Antenatal care—prevention of post-maturity, nition of contracted pelvis, correction of occipito-post position.
2. Accurate diagnosis during labour.
3. Allowance of time and administration of sed during slow labour.
4. Use of forceps only when the cervix is fully the head fixed, and the greatest presenting diameter the pelvic brim, and then only when demanded by signs maternal or fœtal distress.

Anomalies in the Use of Obstetric Forceps

1. The application of forceps is the operation commonly performed in general practice. It is th only operation performed by many pra Many a man who will send a patient to rather than open a whitlow, takes pride in his with the tongs. Yet it is the one common o which many students never see. Under the pres arrangement of providing a fortnight's practica *midwifery* in the medical curriculum, a certa number of Liverpool students, with the 20 cases to their credit, never see forceps appli until they use them themselves in general practice I simply cannot understand this rule: that weeks' residence in a maternity hospital is com pulsory for medical students and another two optional; responsibility rests with the authori who ordain the medical curriculum. It has often stated that the difficulty in teaching midwifer is due to the lack of material—this is not the case Liverpool. If the difficulty is due to lack of dential quarters surely something could have be done about it before this. The experience provide is just about adequate for a student who is to speciali in eyes or orthopædics, or who at any rate is deter mined to undertake no midwifery after he is qualified Surely a student might at least have the option further experience in this department. It is 20 ye since I was a student in another school, but I was qualified I had lived for six months in Rotunda, and attended, not 20, but 120 cases— that experience has stood by me in every case I hav seen *since*.

2. The common use of forceps provides a per example of the proverb : " Out of sight, out of mind. Once the instrument has been applied, its are out of sight and out of touch—so are the and the cervix. Hence it comes that a doctor wh will handle a new-born infant with gentle care, think nothing of applying powerful compressi to a fœtal head, putting his foot against the bed, and, as I have many times been told, pulling wi all his might—and this with the idea of deliverin the mother of a living child. It is an instance extraordinary lack of imagination, and the dates, I believe, from student days. Far too litt time is spent in practical midwifery.

3. Forceps is most often wrongly applied in an effort to save time or to save pain—to shorten the duration of labour. Time is of little or no importance in midwifery, yet to every doctor time is very precious. The ideal obstetrician is one who has no other interests or engagements, who needs no sleep, whose 24-hour day is wholly at the disposal of his patients. Any restriction in time is prejudicial to the practice of obstetrics, yet it is obvious that we must sometimes

ompromise. The point I wish to stress is this: hat if an obstetrician can make an accurate diagnosis, e will be able to compromise successfully and have othing to regret. It is perfectly natural that, when pressed by other work or by agitated relatives, practitioner may say: "For heaven's sake let's et the forceps on and be finished with it!" but, the woman be not ready for delivery, he has failed n his trust, and the punishment, which comes peedily, falls upon the patient. There is no discipline more severe than that imposed by the conscientious practice of obstetrics. Probably the object of saving ime or relieving pain was the reason why forceps were applied in the 20 cases in which we could discover no indication.

This factor is recognised, of course, by midwives. o often, when a midwife brings a patient to see me n her second pregnancy, the first having ended in a orceps delivery, and I inquire why she had forceps n her first confinement, the answer comes, "Because he had engaged a doctor."

4. Forceps is often wrongly applied through rror in diagnosis. Why is it that the idea of putting hand into the vagina to make an accurate diagnosis s more daunting than that of putting on forceps? An anæsthetic is required for either procedure. There is no great difficulty in diagnosis; everyone knows the shape of an infant's head. It is only a matter of careful examination under anæsthesia.

5. Every practitioner is expected to be a specialist n midwifery; he is therefore liable to a loss of prestige if he calls in a second opinion, and when he fails to deliver with forceps at the first try, he is tempted to try and try again, instead of recognising that when forceps fail they are unsuitable.

Occasionally forceps fail because the wrong type of instrument is used. Unless the fœtal head is fixed below the pubis (that is, is distending the vulva), it is quite impossible to pull in the direction of delivery by means of the straight-handled forceps alone. On account of the presence of the perineum, traction with this instrument can only be made forwards and downwards, thus jamming the vertex against the pubic bone and extending the head. If downward traction only be employed, the perineum is severely torn.

The use of an axis-traction handle permits force to be applied in a line continuing the axis of the blades. The pull is therefore an effective downward pull which accommodates itself to the direction of the parturient canal, in which the blades naturally lie. The plane of the blades is indicated by a line upon the shaft, to which an arrow on the axis handle must be kept directed. If the patient be lying upon her back, the pull is made downwards towards the floor, so long as the fœtal head is behind the pubis, and only when the vertex is fixed below the pubic arch may the pull be directed horizontally, and then upwards.

I was called to the hospital one night not long ago. A competent house surgeon had applied straight-handled forceps in a primigravida, under what she considered perfect conditions, and to her astonishment she could not budge the head. I found her diagnosis quite correct; the vertex was presenting with the occiput anterior, the cervix was fully dilated, the whole head in the pelvis. I was told that the scalp had been visible during pains for three hours. Delivery with axis-traction forceps was easily accomplished, without injury to the perineum, and the child was born alive.

6. The appearance of the fœtal scalp during a pain is not necessarily evidence that the head is on the perineum or that the application of forceps is permissible. I have seen the scalp at the vulva when it covered but a projection of a hydrocephalic head, mushroomed above the pelvic brim. We have all been deceived at some time by an enormous caput formed in front of a head impacted in the pelvic brim.

Having, for seven years, done the midwifery of a general practice, I am not ignorant of its dangers, nor of the immense difficulties met with in the single-handed practice of obstetrics. It is by far the most exacting—and always the worst paid—branch of medicine. In what other branch does a surgeon have to be anæsthetist as well? In country practice I have several times given the anæsthetic and put on forceps myself, with no one in the room but a handywoman. The risks undertaken are unpardonable, involving two lives, but until public opinion comes to recognise the importance of obstetrics, the unreasonableness of expecting one brain and one pair of hands to do the work of two, and the absurdity of expecting every newly qualified doctor to be an expert obstetrical surgeon, there will be little decrease in the figures of maternal and fœtal mortality.

In the meantime, however, I see no reason why the misuse of forceps should not disappear from the list of causes of maternal disability and stillbirth.

THE PRESENT POSITION OF PROSTATECTOMY*

BY HUGH CABOT, C.M.G., M.D., F.A.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY OF MINNESOTA GRADUATE SCHOOL; SURGEON TO THE MAYO CLINIC.

WITHOUT going too far back into the more or less accidental performance of prostatectomy, one may date the intentional operation for removal of obstruction from those put forward almost simultaneously by McGill in this country and Belfield in the United States. These were in the later 'eighties of the last century. They were not prostatectomies as we now think of them, and though performed by the suprapubic route, were only partial operations and for this reason only partially successful. Their incomplete success led to the rise during the 'eighties and 'nineties of the operation of perineal prostatectomy in which the French school, typified perhaps by the work of Proust, played an important part. In America Watson, Alexander, and, at a later date, Young made important contributions to this method of approach. Then at the beginning of the present century came the much more complete suprapubic operation, probably first done by Fuller of New York, but developed and popularised by Sir Peter Freyer. As a development or offshoot of suprapubic prostatectomy came the so-called two-stage suprapubic operation, intermittently done during the first ten years of the century, but perhaps first clearly and strongly advocated by Pilcher. This had for its purpose the division of the operation into two stages, the first of which provided adequate and if necessary prolonged drainage, and the second enucleated the prostate through the little, if at all, enlarged wound, and resulted in a considerable diminution in the mortality, particularly in the less favourable cases. Finally, bringing the matter fairly up to date, one should note the so-called one-stage open dissecting operation, first in the United States clearly described and frequently done by Judd in 1914, and so fully developed and beautifully done by Sir John Thomson-Walker and other British surgeons.

---

* An address delivered at the Medical College St. Bartholomew's Hospital, on April 18th.

CERTAIN PRINCIPLES AND THEIR APPLICATION.

In this period of something like 30 years there have become established certain principles, and many of the earlier types of operation have entirely disappeared from present-day practice. Of these principles one may pick out the following :—

(1) *Gradual decompression.*—It is generally accepted that the obstructed and over-distended bladder should be emptied gradually, thereby avoiding the accident of bleeding, but (as I think, more importantly) the resulting acute fulminating infection, involving, if serious, the upper urinary tract.

(2) *Drainage.*—About 30 years ago the importance of preliminary drainage, as a method of improving kidney function and stabilising the conditions in the upper urinary tract, was first clearly stated, and it has become an established principle. It will be obvious that the duration of drainage will depend upon the evidence of derangement of kidney function and the evidence of the ability of the patient to restore the function of the kidney to a reasonably satisfactory level.

(3) Finally, it has become clearly established that successful prostatectomy requires effective *removal of the obstruction*. This may seem elementary, but it must be recalled that the early operations of McGill and Belfield failed because they did not satisfactorily remove the obstruction ; that the convincing success of the operation of Fuller and Freyer was due to the very complete removal of the enlarged portions of the prostate ; and finally, that in those cases in which the prostate is small, fibrous, or contracted, no methods of operation have been as satisfactory as in the cases where there is massive enlargement and the obstructing tissue can be readily and certainly removed.

Bearing these principles in mind, one may dogmatise in regard to the present situation.

Drainage may be established by one of two methods, either by the introduction of an inlying urethral catheter or by suprapubic cystostomy. Urethral drainage is suited to those cases in which it need not be unduly prolonged—a period which may be set at two or possibly three weeks—and in which the catheter can be reasonably tolerated by the patient. Suprapubic drainage is suited to those cases where prolonged drainage, continued for from a few weeks to several or even many months, is indicated in order to stabilise function, and will also be required for those cases in whom the catheter for any reason becomes intolerable. If drainage can be satisfactorily carried out through the urethra we then have at our disposal, as I now believe, two methods of attack. We may either proceed by the now well-known and well-established one-stage suprapubic prostatectomy in which full exposure is obtained, the enlarged portion of the prostate is removed under sight and the bleeding is satisfactorily controlled ; or we may apply a relatively recent, but as I believe important newcomer in this field, a so-called transurethral prostatectomy. It will be noted that I have entirely discarded the operation of perineal prostatectomy, though I am aware that it is still popular with many very able urologists in the United States, and do not doubt that it will continue to remain so for a considerable period. I have, however, come to the conclusion, which at this time I can only state dogmatically, that the newer operation of transurethral prostatectomy will finally push perineal prostatectomy from the stage and that it will do everything which this operation has done for us in the past in an equally satisfactory way and at a lesser risk. For that group of cases which has required prolonged suprapubic drainage we now have, as I think, two procedures at our disposal :—

(1) The *second stage of the so-called two-stage prostatectomy* may be carried out through the suprapubic wound during the earlier weeks without enlarging the wound, and later by moderate enlargement transversely in order to avoid possible injury to the peritoneum. This operation is, of necessity, a blind procedure but has given very satisfactory results in the group of cases in which it has been required, and does not require niceties of exposure essential to the satisfactory control of bleeding in the one-stage operation because the prolonged drainage will be found to have virtually eliminated serious bleeding from the list of possibilities.

(2) *Transurethral prostatectomy.*—Growing experience has, I think, shown that a very considerable group of patients for whom prolonged suprapubic drainage has been required, and for whom, at the time of instituting drainage, it seemed that suprapubic enucleation would be required, will be found after the lapse of many weeks or months with a prostate so shrunken as to come readily into the field admittedly appropriate for transurethral attack. For this group of cases perineal prostatectomy has never appeared to find a large place, though I have never been quite sure why the enthusiastic advocates of the operation did not regard it as a satisfactory procedure for removal of the obstruction even though prolonged suprapubic drainage had been required in the interests of improved and stabilised kidney function.

It will thus appear that I am of the opinion that prostatectomy is rapidly being boiled down to thre procedures : (1) drainage, (2) one-stage suprapubi prostatectomy, or transurethral prostatectomy, an (3) two-stage prostatectomy, either suprapubic o transurethral. I need not burden you with furthe discussion of one-stage prostatectomy or two-stag suprapubic prostatectomy, since they are not new procedures and have become thoroughly establishe in the surgical world. It does, I think, behove m to give some account of the latest candidate fo favour, transurethral prostatectomy, in order t make it clear why I have given it such an important place in the field.

THE TRANSURETHRAL OPERATION.

We should perhaps date the beginning of th procedures which have led up to present transurethra prostatectomy to the introduction by Bottini in th 'eighties of the last century of his cautery knife fo incising the bladder neck. With this instrument introduced through the urethra, an incision was mad through the bladder neck and the obstructing tissu divided by means of an electrically heated blad The operation was difficult of performance, was blind and never became widely popular. The next important step in somewhat the same direction was th introduction by Young, of Baltimore, of his so-calle prostatic punch, an instrument having a large window in its heel and which can be introduced readily int the urethra by means of an obturator. This obturato having been withdrawn, a portion of the obstructin bladder neck then protruded into the window and wa cut away by a circular knife introduced in place of th obturator. This instrument was a very important advance, but as the procedure was not conducted under sight the precise amount and relations of th tissue removed were doubtful, and in a varying but important number of cases troublesome bleeding occurred which might even require suprapubic opening of the bladder for its satisfactory control. An important improvement upon this instrument was introduced by Caulk, who substituted a circular cautery knife for the cold knife of Young, and thus reduced to a minimum or even abolished troublesome bleeding. Except in the hands of its inventor, however, this instrument never enjoyed wide popularity, since the operation was necessarily a blind one and the precise amount of heat developed by the knife was not easily regulated so that there was danger of cauterising the surrounding tissues if the heat was too great, or failing to control the bleeding satisfactorily if the heat was too little. However, the operations of Young and Caulk clearly prepared the field for the developments of recent years. In 1924, Stern, of New York, made an important advance in developing an instrument resembling a cystoscope, by means of which the bladder neck was constantly under view, and through which the introduction of a wire loop, heated by a high-frequency current, could be manipulated in such a way as to pare away portions of the bladder neck. Stern did not succeed in developing this instrument to his entire satisfaction and I believe later abandoned it, but it was pioneer work which has led to the development of a variety of instruments in which the essential principle of complete visualisation of the field and the removal of obstructing tissue by knives, wire loops, or other forms of cutting blade have been developed. At the present time the operation is being done with a very considerable variety of instruments, utilising these general principles. Among the instruments most employed and most successful at the present time may be named those of Davis, McCarthy, and Bumpus. By means of all of these a complete view of the bladder neck is obtained, the obstructing tissue is accurately located and then accurately removed by methods which control the bleeding.

Coming now to the principles involved in this operation, it must be at once admitted that they revert to the earlier types of partial prostatectomy and would seem thereby to expose themselves to the disasters which befell the operations of McGill and Belfield. On the other hand, it will be widely recognised that prostatic obstruction bears little or no relation to the size of the prostate, that very large prostates may produce no obstruction, whereas the most complete obstruction can be caused by glands which show no enlargement and may even be smaller than normal. We are thus forced to the conclusion that it is not the size of the prostate but the position of the obstructing tissue which is important. The work of Young, Caulk, and their modern successors appears to have demonstrated that the obstructing tissue is that which lies between the verumontanum in front and the inter-ureteric bar behind. The success which has apparently attended the transurethral operations which remove tissue in this location suggests that the lateral lobes which are commonly the most palpable and the most obvious play a relatively small part in the obstruction, and there is at least a strong suggestion which can develop into a certainty only with further experience, that even very considerable enlargement of the lateral lobes may be neglected if a clear channel is established through the region above mentioned. The operations with the instruments of Davis, McCarthy, or Bumpus remove the tissue in relatively small pieces, but particularly with the instrument of Bumpus the tissue is not destroyed by electrocoagulation and can thus be submitted to pathological examination which is occasionally important in the discovery of early cases of malignant disease. Davis, whose experience is perhaps the largest, removes large quantities of tissue and does not hesitate to devote considerable time, amounting occasionally to one or even two hours, to the procedure. Bumpus, on the other hand, is satisfied with removal of somewhat less tissue and his operations are of much less duration. In the cases operated by Bumpus and his colleagues at the Mayo Clinic the average weight of tissue removed is about 5 g., the extremes being 20 g. and 1 g.

USES AND LIMITATIONS.

Having thus briefly described the nature of the operation, it is proper to inquire upon what authority it has intruded itself into the field and what are its present limitations. The best evidence of its right to be considered a very important procedure appears to me to rest upon the experience of Caulk, with his, as I think, less satisfactory apparatus, but with an experience going back over 15 years, and more recently upon the work of many urologists other than those above mentioned, who, together, have presented for our consideration a large group of patients showing satisfactory results over periods varying up to as much as ten years. Their accumulated experience appears to me to show conclusively that operations done in this way do in fact satisfactorily remove obstruction. The next important considerations are those of the operative risk and the duration of hospital confinement. There are enthusiastic advocates of the operation who express the opinion that there is no mortality properly attributable to the operation. Our experience at the Mayo Clinic, which now runs to about 250 cases, does not appear to me to justify such great optimism. Our mortality from all causes during a period of six weeks from the operation is somewhat under 3 per cent., and it does not seem to me likely that in any large series of cases a much lower mortality will be obtainable. In any operation done upon patients in this age-group it does not seem to me helpful to attempt to exclude from mortality statistics patients alleged to have died from vascular accident or of intercurrent pneumonia, thought not to be connected with the operation itself. It appears to me wiser to credit ourselves with all of this mortality on the general ground that the patients probably would not have died if no operation had been undertaken. Moreover, I do not think that it is helpful to paint the lily, and if this method of operation will in fact relieve the obstruction at an operative risk between 2 and 3 per cent. it will achieve better results than have yet been forthcoming from any other operation for prostatectomy.

Perhaps one of the greatest advantages claimed, and I think substantiated, from this operation is the relatively brief confinement as compared with any other method. At best the perineal operation confined patients for a period of three to four weeks, not including the period of drainage. For the suprapubic operation a somewhat longer period was generally necessary. The transurethral operation can be expected to require confinement varying from three or four days to two weeks at the maximum, and averaging between seven and ten days. At the end of this period the patients are up and about, completely emptying their bladders and in a condition safely to leave the hospital and perhaps even the immediate care of the surgeon. This is a very great improvement over other methods and deserves being marked up to the credit of the procedure.

It will doubtless be objected that as only a relatively small amount of tissue is removed recurrence will be more likely. To this one can only reply that recurrence has not been unknown after relatively complete operations by the suprapubic or the perineal route, though it must be admitted that such recurrences were relatively uncommon. It must be admitted that at the present time there is no commanding array of patients treated by this method more than five years ago from whom conclusions can be drawn. There are, however, a considerable number over five years some even more than ten years, in whom recurrence has not taken place. Furthermore, it is not inconceivable that an operation of relatively trivial risk might properly be repeated after a lapse of four or five years and the patient yet be better off than had he been forced to withstand the fundamental disturbance of a more serious operation.

THE FIELD OF APPLICATION OF TRANSURETHRAL PROSTATECTOMY.

It is proper, I think, in conclusion, that I should state my own view as to the proportion of cases of obstructing prostate which may properly be treated by this method. It will generally be admitted that the operation is most obviously suited to patients with small glandular hypertrophies and in general to the smaller types of obstruction. I am still doubtful whether the operation can be satisfactorily applied to patients with very great enlargement of the commissural subcervical glandular structures, in general the group commonly referred to as median lobe enlargement. Some of these enlargements reach very great size and project backward, entirely covering the trigone and in some cases are more or less pedunculated. For this group I have hesitated to advise transurethral prostatectomy, though I am aware that it has been successfully employed in such cases. For the present at least I should prefer for these patients the suprapubic method of attack. I am also hesitant in regard to patients with large lateral lobes which have herniated backward through the vesical sphincter and come to lie in an obstructing position in the mid-line. The transurethral approach seems to me considerably handicapped in dealing with this group. Here suprapubic prostatectomy is at its best and I think further experience, at least, is required before admitting that the lesser procedure will produce wholly satisfactory results. For the moderate enlargements such as would be classified as one and two on a scale of four, I am satisfied that the transurethral attack is well suited and has demonstrated satisfactory results. At the present time at the Mayo Clinic something like half of the cases of prostatic obstruction appear to us wholly suited to this method, and I observe that the proportion which we regard as suitable has steadily increased during the last two years.

Briefly stated then, my opinion is this. I will not, at the moment, go "sled-length" with the enthusiasts who take the view that any obstructing prostate can be satisfactorily dealt with in this fashion. I shrewdly suspect that with growing experience and with the inevitable improvements of technique something like three-quarters of the cases will, within the next few years, come properly within the field of this operation. It will be observed that it is equally applicable to the patient who requires but little urethral drainage and to the patient who has required prolonged suprapubic drainage, that it carries beyond question the lowest mortality of any of the modern operations, and that it appears to give satisfactorily permanent results.

ENDO-URETHRAL TREATMENT OF ENLARGED PROSTATE *

By Joseph F. McCarthy, M.D.,

DIRECTOR, DEPARTMENT OF UROLOGY, NEW YORK POST-GRADUAT
MEDICAL SCHOOL, COLUMBIA UNIVERSITY.

The history of prostatic obstructions with it manifold sequelæ, near and remote, is a fascinatin one. Not the least interesting feature of this subjec in retrospect has been the types and personalitie of the workers in this field during bygone year How prescient was the clinical sense of these men For, long before surgical enucleation was eve considered, many attempts were made along suc lines as galvano-cautery incision via perineum an urethra, of bars and other prostatic obstructions a the vesical neck.

These discerning attempts were only occasionall successful, not because of mistaken clinical concep but for the very good reason that the collater sciences had not yet developed to the stage wher they could supply the exacting optical and electric equipment essential to this highly technical procedur We are back where our predecessors began and to-day equipped with better instrumental appliances, ar able to accomplish the objective they visualise but failed to achieve.

Fortunately for those of us contemplating th advent of senescence there comes this note o optimism—this pleasant prediction—that prostati obstructive manifestations can and should b recognised at their incipiency, that at such a stage o development, these early indications of later ill may be easily and expeditiously removed by relatively minor and precise surgical instrumenta procedure.

To-day there is crystallised before us the combine efforts of sustained research during the past 50 year The basic concepts were laid down in the early year to be built upon, piece by piece, as time went o Notable among the builders upon that early founda tion are to be mentioned Young, Caulk, Stein, Davis Luys, and Foley.

Some 19 years ago I reported two cases of obstruct ing prostates apparently cured by endo-urethra instrumental measures. The immediate results wer spectacularly successful. Later attempts wer unsatisfactory because of obvious electrical limitations Here the offending prostate was removed by mean of an Oudin high-frequency current.

My early attempts in the development of visualise cutting loops date back to 1922. They are still i our possession, and in the light of subsequent develop ments present an interesting collection. At tha time visibility had to be sacrificed to adequat insulation against spark-gap currents, which rendered cutting electrodes so bulky as to be impractical Neither did I regard the direct or indirect type of vision incorporated in the endoscopes of that day as wholly suitable. It was not, therefore, until the advent of the new amphitheatre or panendoscopic system of vision and the later development of the revolutionary electrical machine, both of which were devised by Mr. Frederick Wappler, the brilliant son of his distinguished father, Reinhold, that this long sought-for goal could have been approximated.

Whatever success may attend the procedure herein outlined I cheerfully ascribe to Caulk.

---

* Read before the Southeastern Surgical Congress, U.S.A., March 7th, 1932.

For it was he who demonstrated that instrumental endo-urethral approach in the management of prostatic hypertrophy was a feasible procedure, and it was the inspiration of his work that, in the face of many discouragements, kept us everlastingly at it.

This new technique constitutes a departure from the methods heretofore described, in that, with amphitheatre vision, one sees the entire prostatic urethra in tubular perspective, as though one looked from an observation car into a well-illuminated tunnel. Thus one sees the number, type, and extent of prostatic boulders that encroach upon its lumen. In simplest terms, with this visual survey in mind and under the most precise observation the cutting loop which is fitted to a rack and pinion, is adjusted behind the obstruction, the cutting current started with a foot switch and the loop withdrawn by means of the pinion near the eye-piece, bringing with it a tubular cast of prostatic tissue comparable in size to the loop. The loop when charged with this new current, cuts under water smoother and cleaner than the sharpest scalpel and what is very important, coagulates superficially as it cuts. It thereby acts, when properly regulated, as an effective hæmostatic agent. Incidentally its trajectory, because of the mechanical arrangement, is as straight and precise as though it travelled on rails.

In other words, 90 per cent. of prostatic encroachments, malignant or otherwise, and however dense, may be regarded as so much plastic material, to be removed seriatim by a loop charged with a new type of cutting current, upon the cutting effectiveness of which the presence of water seems to exert no discernible deterrent action.

The obvious interpretation is that thus equipped one may remould the prostatic urethra at will. This is borne out by the experience of my associates and myself in a large series of cases of all types, from the simplest fibrosis to advanced malignancies, and all degrees of urinary retention. Further, lest there be the slightest misapprehension, the assertion is here made that this procedure is more precise and more surgical than is that of open prostatectomy. It may further be added that adequate provision is made for any eventuality.

The rationale as I conceive it is, that here we have a tubular structure, the lumen of which is encumbered and distorted by irregular encroachments—that we should have tubular vision for its adequate comprehension—that our objective is, or should be, restoration of that lumen to normal or a moderate exaggeration of its normal tubular character. In other words, an operation of canalisation rather than excavation.

It has seemed to me inexpedient to involve this communication with technicalities. It is, however, reasonable to assume that if Caulk, Davis, myself, and others, equally competent, can effect by means of this route, with a negligible mortality, brief hospital domicile, minimal post-hospital morbidity, complete symptomatic relief, functional restoration, and relative permanency to date, in 90 per cent. of all types of prostatics, how much simpler will it be to apprehend such cases at their onset and prevent them from experiencing that period of senile travail, when their mental capacity is at its peak, and their physical resistance in decline? If internists and general practitioners will come to a realisation of the tremendous economical and sociological importance of the early recognition of prostatic obstructive manifestations, and see to it that they are corrected at their incipiency, the sequelæ of prostatism should no longer be a matter of common observation.

FOCAL SEPSIS AS A CAUSE OF NEPHRITIS

By A. Cecil Alport, M.D. Edin., M.R.C.P. Lond.,

ASSISTANT TO DIRECTOR OF MEDICAL UNIT, ST. MARY'S HOSPITAL, LONDON.

Before dealing with focal sepsis as an ætiological factor in nephritis it is, I think, necessary to make a few remarks in regard to the classification of diseases of the kidneys, and particularly to the term "nephrosis," which was introduced by Müller [1] in 1905, and subsequently approved by Munk,[2] Volhard and Fahr,[3] and others. Three years ago I suggested [4] that, from the clinical standpoint, it seemed difficult to justify this addition to the terminology of kidney disease; and since then Dr. Dorothy Russell,[5] in her excellent monograph on Bright's disease, has shown that, according to the histological evidence, the mild kind of toxic nephritis (mitis) may begin as a pure parenchymatous degeneration or nephrosis. It is well known, of course, that in cases showing both degenerative and inflammatory changes in the kidney even the expert pathologist finds it difficult to determine whether the primary lesion was a degenerative or an inflammatory one.

The modern conception of nephrosis is that of a primary degeneration of the renal tubules without any involvement of the glomeruli. Recently, however, Izod Bennett, Dodds, Robertson, and Baker [6] have suggested that many cases of secondary contracted kidney with death from uræmia may be the result of progressive changes in the glomeruli following severe damage to the tubal epithelium. This is apparently a new interpretation of the old idea that the large white kidney contracts down and becomes the secondarily contracted small white kidney. Clinically nephrosis is associated with much œdema and albuminuria, hypercholesterolæmia, normal retinæ and cardiovascular system, and no disturbance of renal function as estimated by the excretion of urea. Dr. Russell's recognition of nephrosis as a mild type of inflammation of the kidneys (nephritis mitis) again takes us back to the older view that cases with such symptoms are simply subacute manifestations of nephritis. I have, therefore, in this article made no distinction between subacute nephritis and nephrosis when discussing the ætiology and treatment of these conditions.

The term semi-chronic nephritis refers to the contracting stages between large white kidney (subacute nephritis) and small white kidney (chronic parenchymatous nephritis).

Ætiology of Nephritis

It can reasonably be held that there is probably a toxic factor at the root of all cases of Bright's disease. This is well seen in the acute types which follow the acute infective fevers, particularly scarlet fever and diphtheria. Damage to the glomeruli, followed by tubular degeneration, is also caused by the toxins of pregnancy and secondary syphilis, and by tonsillitis and certain chemical poisons. But what we fail, as a rule, to recognise is the fact that in those cases in which there is a transition to the subacute and chronic stages of nephritis there is often a secondary or residual focus of infection in the tonsils, antra, sinuses, teeth, or perhaps the intestines, which may account for the failure of the acute renal condition to subside completely. Moreover, cases of subacute nephritis with marked œdema and albuminuria, and the semi-chronic varieties with less œdema and albumin in the urine, but with some urea retention and cardiovascular changes, are often the result of focal sepsis. These cases usually begin insidiously; their rate of progress varies and, unless the focus of infection is recognised and eradicated at an early stage, a progressive deterioration may occur which sooner or later ends in the death of the patient from pneumococcal infection of the œdematous tissues or from renal or cardiovascular failure.

From the point of view of organismal infection of the kidneys, Rosenow's work on the elective localisation of streptococci suggests that oral sepsis may be the focus of infection of bacteria having selective affinity for the urinary tract. Bumpus and Meisser [7] have described swelling and areas of hæmorrhage and necrosis in the medulla of the kidneys of rabbits after intravenous injection of streptococci from infected teeth or tonsils.

Hartzell and Henrici produced definite suppurative changes in rabbits after inoculation with streptococci, but did not describe anything indicating chronic interstitial nephritis. The presence of chronic inflammatory or degenerative changes, however, would necessitate a long-continued infection, which is difficult to produce in an animal; thus experimental evidence of toxæmic kidney is not very conclusive. In the course of research on streptococcal injections in rabbits, I found albumin in the urine of four of the animals which developed pyæmic joints but recovered under treatment with fixation abscesses.

The details are as follows:—

Rabbit 1.—Normal control—no albumin in the urine.

Rabbit 2.—Twelve months after intravenous injection of virulent hæmolytic streptococci: definite cloud of albumin found in the urine, both on boiling and after acidifying with nitric acid.

Rabbit 3.—Ten months after injection: a faint trace of albumin present; re-examination of the urine eighteen months later showed no albumin.

Rabbit 4.—Three months after injection: a cloud of albumin (0·15 per cent.).

Rabbit 5.—Three months after injection: a definite trace of albumin.

The effect of a toxin upon the kidney depends: (a) upon its virulence; (b) upon the length of time it continues to be excreted, and thus is able to excite degenerative or inflammatory reaction; and (c) upon the resistance of the kidney tissues to toxic action. Although the subacute type of nephritis is the more likely to result from a toxin of comparatively low virulence passing through the kidney over a prolonged period, it is possible that even the very chronic cases, which commence insidiously and do not appear in the consulting-room until marked contraction of the kidneys has occurred, may also be due to this cause.

If in a case of nephritis the tonsils or antra are found to be infected, and if these are promptly and efficiently dealt with by surgical means, a definite cure may result. I have also treated cases of œdema and albuminuria with vaccines made from hæmolytic and viridans streptococci obtained from the stools, but although temporary improvement took place there was always a return of the albuminuria. In all these cases, however, a further examination by the ear, nose, and throat department and by X rays showed infected tonsils or antra. These patients have since been operated upon, and the results obtained will be referred to later. Vaccine treatment is thus only worth trying in cases in which there is definitely no focus of infection in the mouth or sinuses or in which the removal of a focus of infection is an impossibility.

The following illustrates the course of a typical case of subacute nephritis which had become semi-chronic:—

CASE 1.—A girl, aged 16, was admitted to the Medical Unit wards of St. Mary's Hospital, suffering from marked general anasarca, distressed breathing, cyanosis, severe headache, frequent cough with clear sputum, and advanced cardiac failure. The history showed that she had been in good health until eight months previously, when her face became swollen. She was sent to bed by her doctor, but the œdema became general and a month before admission she developed headache, nausea and vomiting, and cough with expectoration which on one occasion was streaked with blood. When I saw her in hospital, her pulse-rate was 112, blood pressure 180/130, apex-beat 1" external to mid-clavicular line in the fifth space, systolic bruit over mitral area, aortic second sound reduplicated, and lungs œdematous. Urine: albumin + + +, and some blood present. Blood-urea 74 mg. per 100 c.cm. Urea-concentration test: maximum concentration 1·5 per cent. and minimum 1·5 per cent. Urinary chlorides content: 0·0936 g. per cent. NaCl. Thus the blood-urea was high, chlorides were retained, and there was moderate impairment of renal function as shown by the urea-concentration test; the high minimum concentration indicates that there was very definite retention of water as well.

Examination of her teeth showed advanced dental sepsis; pus exuded from the gums and, on extraction of the first left lower molar, pus was evacuated from the socket in quantity. Her sinuses were then radiographed, and marked opacity of the right maxillary antrum was found; this was due to the presence of pus and was drained by the extraction of a tooth. The œdema diminished on a diet containing full amounts of protein and the administration of 20 g. of urea every four hours, but her general condition was such that it was impossible to extract any more of her teeth or to deal effectively with the septic condition of her mouth and antrum. The result was steadily progressive changes in kidneys already badly damaged by long-continued excretion of virulent toxins, and a hopeless prognosis.

Towards the end she became more œdematous, and she died from cardiac failure a few weeks after admission.

Autopsy revealed hypertrophy and dilatation of the left ventricle, hypertrophy of the right ventricle, and cloudy swelling of the myocardium. Several small infarcts were found in the lungs. There were about eight pints of fluid in the peritoneal cavity, one pint in each pleural cavity, and ten ounces in the pericardial sac. The kidneys were slightly enlarged, pale, with small subcapsular hæmorrhages, and the cut surface was flecked with yellow in the intermediate zone. Microscopical examination showed a kidney of the semi-chronic type, a contracting stage between subacute nephritis and secondarily contracted small white kidney—the nephritis actis, in the intermediate stage, of Dr. Dorothy Russell.

I am of opinion that if a focus of infection had been sought for at an early stage of the disease, and, when found, had been suitably dealt with, this patient would have recovered. The history, treatment, and course of the next case show why, in my opinion, the discovery of focal sepsis is of such importance in kidney disease, especially in the œdematous cases which have been classified under the name "nephrosis."

CASE 2.—A woman, aged 46, was examined by her local doctor on June 1st, 1930, before her annual holiday; the doctor states that at that time she was quite fit and that her urine was normal, with no albumin in it. Five weeks later she came to the out-patient department complaining of swelling of her legs, and on examining her urine I found it contained albumin. There was no history of previous kidney disease. As her teeth and gums appeared to be healthy, I referred her to Mr. Cecil Graham for an opinion as to the condition of her throat and sinuses. Mr. Graham reported that the tonsils were small but septic, and that both antra were rather opaque—probably infected, and he decided to take her into his wards for operation.

She was admitted to St. Mary's Hospital on July 20th, 1930, but by this time the œdema had increased to such an extent that Mr. Graham did not feel justified in operating, and he transferred her to the medical side for preliminary treatment. On admission to the Medical Unit wards it was found that her legs, body, and face were extremely œdematous. Her urine contained albumin + +, and a little pus. The blood-urea was 17 mg. per 100 c.cm. The urea-concentration test was normal, the maximum concentration being 3·4 per cent. and the minimum concentration 1 per cent. There was a marked defect in water excretion, only 264 c.cm. of the 850 c.cm. taken being excreted in four hours. The specific gravity, however, ranged from 1022 to 1005, and did not remain fixed in the vicinity of 1011, as occurs in the more chronic types of nephritis. The cardiovascular system showed no abnormality.

She was given a salt-free diet with full amounts of protein, and large doses of urea, 20 g. every four hours. The œdema completely disappeared after about a fortnight's treatment on these lines, and on Aug. 15th, she was sent home, as the ward was being temporarily closed. Ten days later, she was found to be more œdematous than ever, so much so that she was unable to wear her ordinary clothes, and she was readmitted in a dressing-gown. Another course of massive urea dosage, however, reduced the œdema again and on Oct. 8th, 1930, Mr. Graham performed tonsillectomy and washed out her antra. Swabs taken at the operation showed hæmolytic and viridans streptococcal infection of the tonsils, but no definite infection of the antra. She was discharged to a convalescent home and has made a complete recovery.

Her present condition is as follows: She states she feels perfectly well; there is no sign of œdema and no albumin, blood, caste, or pus in the urine; blood-urea 26 mg. per 100 c.cm. Urea-concentration test: maximum concentration 2·5 per cent.; minimum concentration 0·3 per cent. She passed 763 c.cm. of the 850 c.cm. of water taken in 6 hours. Heart and vessels normal. Blood pressure: 120 systolic and 82 diastolic. Fundi normal.

This is a classical example of what should be the course of subacute nephritis (nephrosis), but unfortunately the part played by the toxins of focal sepsis in the ætiology of some of the less acute types of nephritis is not as yet generally recognised. I feel convinced that a careful search for septic foci in the mouth, throat, and antra should be made as routine practice in all cases of nephritis, but particularly in the types characterised by much albuminuria and œdema. Moreover, the examination should be carried out by ear, nose, and throat and dental specialists, and radiographs of the sinuses and teeth should not be neglected. Until this is done and the focus of infection, if found, eradicated by surgical means, many cases such as the first one described will continue to go to the post-mortem room instead of to a convalescent home.

It is by no means uncommon also to find albumin in the urine of young persons who are being examined for life insurance or for posts in the Civil Service, banks, and other institutions. Usually there is no history of previous kidney trouble or any infectious disease to which the albuminuria can be attributed. Apart from functional albuminuria, a proportion of these cases may be due to focal sepsis, and no pains in my opinion should be spared to eliminate its possibility as an ætiological factor; failure to do so may result in some form of nephritis at a later date.

REDUCTION OF ŒDEMA BEFORE OPERATION IN CASES OF NEPHRITIS.

Massive doses of urea are necessary for this purpose, and can be given without any ill-effects. It is customary to give 20 g. every four hours until the œdema disappears. Experimenting upon a normal person I found that by giving 30 g. of urea every four hours for 12 doses the blood-urea rose from 28 mg. to 208 mg. per 100 c.cm. after the final dose, and fell to 54 mg. per 100 c.cm. 30 hours later. The amount of urine passed, on an average, in 24 hours, whilst taking this dosage was 3773 c.cm. (133 oz.)—nearly three times the normal output.

In Case 2 the patient took 20 g. every four hours and the blood-urea rose from the normal, 17 mg., to 122 mg. per 100 c.cm. after 11 doses, and fell to 36 mg. per 100 c.cm. 24 hours later. The output of urine was more than doubled during this time, and the œdema rapidly disappeared. Urea in large doses is undoubtedly the best medical method of treating marked œdema in nephritis.

FURTHER CASES ILLUSTRATING THE ASSOCIATION OF NEPHRITIS WITH FOCAL SEPSIS.

The following examples were taken from a series of 20 cases in which a routine search for focal sepsis was carried out, and in every one of which focal infection was found. The cases comprise acute, subacute, semichronic, and chronic nephritis. The results obtained by the removal of septic foci are briefly described.

CASE 3.—Acute hæmorrhagic nephritis. A boy, aged 2½ years. Admitted for sore-throat, due to septic tonsils, vomiting, and marked hæmaturia. Tonsillectomy performed. Three years later the patient was found to have no albuminuria or other sign of nephritis.

CASE 4.—Acute hæmorrhagic nephritis. Girl, aged 3½ years. Admitted for drowsiness, pallor, puffiness of the eyelids, and much blood in the urine. The tonsils were found to be septic and were enucleated. Examined after two years, the urine was normal and the patient had completely recovered.

CASE 5.—Acute nephritis. Boy, aged 4½ years. On the day before admission for removal of infected tonsils he developed swelling of legs and face. On admission: marked œdema of eyelids, abdomen, and legs. Enlarged inflamed tonsils and cervical adenitis. Urine contained 0·4 per cent. of albumin, some blood, and a few casts. Later, discharged to convalescent home without tonsillectomy, and with a little albumin in urine. A year afterwards there was no albumin in his urine, no casts, and he had apparently recovered without the removal of his tonsils.

CASE 6.—Acute nephritis. Girl, aged 11 years. History of a rash, headache, nausea, and drowsiness, five weeks previously, for which she was confined to bed for three weeks. On admission to hospital, on Dec. 14th, 1930, her face was pale and pasty and her urine contained blood and albumin. Renal tests showed normal kidney function. Tonsils enlarged and infected. Tonsillectomy performed on Feb. 22nd, 1931. A case possibly of scarlet fever followed by nephritis; the kidney condition cleared up and there were no signs of nephritis nine months after tonsillectomy.

CASE 7.—Acute nephritis. Girl, aged 9½ years. History of admission to hospital, in January, 1929, suffering from chorea; tonsillar enlargement was noted at the time. Admitted again in December, 1930, for headaches, puffiness under the eyes, and hæmaturia; she also had hyaline and granular casts in her urine, but her kidney function was normal except for some impairment of water excretion. Ten months later her condition was as follows: no œdema, 0·7 per cent. of albumin in urine, a few red blood corpuscles and pus cells, no casts. She refused to come into hospital for tonsillectomy.

Of the above cases of acute nephritis, three recovered completely after tonsillectomy. One has apparently recovered without operation, although he still had large and infected tonsils, and should be operated upon to prevent a recurrence of his nephritis. The other case has a history of tonsillar enlargement not operated upon, and still has some albumin and a few red blood corpuscles in the urine.

CASE 8.—Boy, aged 13 years. He was in hospital in 1927 with œdema and albuminuria due to subacute nephritis. In October, 1929, he still had œdema and 0·15 per cent. of albumin in his urine. No nitrogen retention, but water excretion was somewhat impaired; he passed only 545 c.cm. out of 850 c.cm. taken by mouth in four hours. His tonsils had been removed some years previously. A mixed streptococcal vaccine, prepared from the stool, was used for four months, and the albuminuria and œdema disappeared.

In February, 1931, the patient caught a cold and developed puffiness of the lower limbs; albumin in urine 0·05 per cent. Examination of nose and throat showed infection of the right antrum and a remnant of one of the tonsils. He was operated upon on March 19th, 1931, and six weeks later the œdema and albuminuria had cleared up again. He then developed boils, and a faint cloud of albumin appeared in the urine. A streptococcal vaccine cured the former, but a trace—0·02 per cent.—of albumin remained in his urine for some time. On Dec. 19th, 1931, his urea concentration and water excretion were normal, and he had no albuminuria, no casts, and no œdema. His general condition is greatly improved, and he is back at school.

CASE 9.—Semi-chronic nephritis. Girl, aged 17 years, attended out-patient department on Jan. 14th, 1930, and was found to have swelling of ankles and puffiness of eyes, and albumin in urine. She had been in bed for seven weeks in Princess Louise Hospital when five years of age, suffering from kidney trouble. Examination of her stools showed a mixed streptococcal infection; she received autogenous vaccine treatment for six months and the albumin and œdema disappeared. Two months later a trace of albumin was again found in the urine and her nose and tonsils were examined by Mr. G. D. Robertson, who performed double antrotomy on Sept. 9th, 1931. There is now no œdema of eyes or legs, no albuminuria and no casts in the urine. Her blood pressure is 115/60, and she is back at work.

Case 10.—Boy, aged 16 years. Admitted to St. Mary's Hospital on May 21st, 1929, suffering from subacute nephritis with marked œdema and albuminuria. His urea concentration was good, but of 20 oz. of water taken by mouth, 10 oz. were still retained at the end of ten hours, showing marked defect of water excretion. His blood pressure was 142/108, and there was accentuation of the aortic second sound. Stool examination showed hæmolytic, viridans, and non-hæmolytic streptococci in large numbers. An autogenous vaccine was injected for three months. During this time his urine contained a trace of albumin; his eyelids were slightly puffy, there was some anæmia and he was marked "unfit for school." As the improvement following vaccine treatment was disappointing, his nose and throat were examined and double antrotomy was performed in April, 1931. Condition on Sept. 30th, 1931, was as follows: No albumin or casts in urine; maximum urea concentration 2·6 per cent.; minimum 0·3 per cent.; water excretion good: passed 627 c.cm. out of 850 c.cm. taken by mouth in two hours. He has now no puffiness of eyelids or pitting along shins; has left school and is at work in a camera factory.

Case 11.—Pyelonephritis. Woman, aged 29 years. History of nephritis of six years duration following pregnancy. Admitted on April 20th, 1931, for headache, drowsiness, œdema, dimness of vision, and abdominal pain. Blood pressure 232/190. Hæmolytic streptococci, pus, and albumin in urine. Blood-urea, 43 mg. per 100 c.cm. Maximum urea concentration 2·1 per cent., minimum concentration 0·4 per cent. Water excretion somewhat impaired—passes only 24½ oz. out of 30 oz. of water taken by mouth in six hours. Tonsils which showed marked infection, were removed on May 21st, 1931.

Six months later, cardiac hypertrophy and accentuated aortic second sound present. Blood pressure 228/155. Considerable anæmia. Urine 0·05 per cent. of albumin; a hyaline cast and a pure growth of streptococci of fæcal type were found. She also has uræmia dyspnœa at night and there has been no improvement in her condition following the tonsillectomy and subsequent vaccine treatment. Improvement in this case, however, was not to be expected in view of the fact that the kidneys had been affected for six years and nothing had apparently been done, until her admission to this hospital, to eradicate either the tonsillar or the urinary infection, by which time serious renal involvement had occurred.

Case 12.—Chronic nephritis, woman, aged 24 years. History of diphtheria eleven years ago, followed by kidney trouble, for which she had been detained in hospital for five months. Œdema and albuminuria occurred after childbirth a year ago. Admitted to hospital six months later with albumin, blood, and hyaline casts in urine. Blood pressure 130/90. No œdema. Renal function tests showed no nitrogen retention but some defect in water excretion. Tonsils enlarged; hæmolytic and viridans streptococci found on culture of swabs. Some dental sepsis present. Tonsillectomy performed. Six months later kidneys showed normal renal function, but there were still some albumin and a few hyaline and hyalogranular casts in the urine.

This is another case in which the tonsillar infection was of long standing, the kidneys becoming progressively damaged; the response to tonsillectomy was thus not so marked as in cases of more recent origin, treated by the removal of septic foci.

Case 13.—Semi-chronic parenchymatous nephritis. Married woman, aged 34 years. Induction of labour in January, 1930, because of albuminuria and œdema. Admitted to St. Mary's Hospital on June 2nd, 1930, suffering from slight œdema of face and legs. Albumin 0·4 per cent., blood pressure 145/98. Blood-urea 48 mg. per 100 c.cm. Maximum urea concentration 2·5 per cent. Minimum concentration 2·1 per cent. Volhard's water test showed marked retention, only 267 c.cm. out of 850 c.cm. taken by mouth being excreted in four hours. On Feb. 27th, 1931, she still had œdema of her legs and 0·35 per cent. of albumin in her urine. As her condition was not improving, her tonsils, which were found to be infected, were enucleated, and the antra cleared. When seen six months later she had a trace of albumin in the urine, and some œdema of her legs, but she was back at work.

Case 14.—Semi-chronic nephritis. Woman, aged 41 years. History of dental trouble and bleeding from the gums. In November, 1929, a six and a half months' pregnancy was terminated in Queen Charlotte's Hospital because she became "unconscious." Admitted to St. Mary's Hospital in December, 1930, for headache, dyspnœa, anæmia, general weakness, and some œdema of the legs. Is very deaf. Blood pressure 210/110; heavy cloud of albumin in urine. Maximum urea concentration 3·4 per cent. and minimum 1·7 per cent. Volhard's water test showed some inefficiency of the kidneys. She only passed 640 c.cm. out of the 850 c.cm. taken in six hours. Blood-urea, 41 mg. per 100 c.cm. Hæmolytic and viridans streptococci found in the throat and the hæmolytic variety in the fæces. Both tonsils and antra were infected. Tonsillectomy performed on Feb. 25th, 1931, and antra cleared up.

Oct. 7th, 1931. Her general condition since the operation remains much the same. She still has marked secondary anæmia. The urine contains a faint trace of albumin and one hyalo-granular cast was found. Maximum urea concentration 2·7 per cent. and minimum 0·4 per cent. She passed 564 c.cm. out of 850 c.cm. of water taken by mouth in two hours, which is about the normal amount for the time, and compares favourably with the findings in December, 1930. This patient, in common with many other cases of nephritis following pregnancy, had a definite infection of tonsils and antra; moreover, the response to operative treatment, because of long-continued damage to the kidneys, was not nearly so marked as in early cases, particularly in non-pregnancy ones.

It is probable that focal sepsis plays a definite part in the ætiology of the nephritis associated with pregnancy, even if it is not the actual cause of the condition; thus it should be sought for in the early stages of pregnancy with albuminuria, and, what is more important, eradicated if found. Although in antenatal clinics it is, no doubt, customary to have a look at the throat and teeth, this in itself is not sufficient; the examination should be carefully carried out by ear, nose, and throat, dental, and radiological specialists. It is comparatively easy to miss small infected tonsils, sepsis at the apices of the teeth, and antral infection. One case I sent to the ear, nose, and throat department for examination showed only a slight dimness of the right antrum on transillumination; this was confirmed on radiography, but it was not considered that there was sufficient evidence of infection to justify operation. On opening the antrum, however, it was found to be full of pus, the explanation being that the antrum discharged itself from time to time and that it was empty at the time of the X ray examination.

Vaccine Treatment in Nephritis

Vaccines should be tried only in cases in which surgical interference is impossible—e.g., in streptococcal excess in the intestinal canal. The streptococci of pathological significance are usually the hæmolytic and viridans varieties. Streptococci may also be found on culturing catheter specimens of the patient's urine. In most cases, however, the urine proves to be sterile. The presence of an organism, moreover, is usually the result of contamination. A negative finding does not imply the absence of nephritis, because the damage to the kidney is due, as a rule, to a toxin and not to the direct action of the organism.

The dosage of vaccines is important: one should begin with 0·1 c.cm. of a vaccine containing 5,000,000 organisms in each c.cm., and work up, at five- to seven-day intervals, to 1 c.cm. of a preparation containing 500,000,000 organisms in each c.cm. A local reaction at the site of injection, an increase of albumin or blood in the urine, or a general reaction with malaise and headache, are indications for cutting down the dosage.

Vaccines have no effect in clearing up septic foci in the tonsils, sinuses, or sockets of the teeth; in these conditions an operation is essential. Moreover, the results obtained from the injection of vaccines prepared from stool cultures tend to vary so greatly that it is impossible to venture an opinion as to their eal value. If a patient is treated with vaccines and the condition fails to respond, a further search should be made for dental, tonsillar, and sinus infection, and should include radiographic examination if these have not been made previously. As a last resource, the stools may be re-examined, because the disappearance of one type of streptococcus may result in the growth of another strain which has been kept down by the original organism ; a fresh vaccine containing this strain would then be required for a further series of injections.

The comparative failure of vaccine therapy is one of the great tragedies of medicine, but we have not as yet, I think, touched the fringe of this type of treatment.

Comments

1. It is an accepted fact that tonsillitis is a cause of acute nephritis. Paterson and Wyllie [8] have shown that 85 per cent. of cases of acute hæmorrhagic nephritis in children are due to tonsillitis or associated conditions, such as cervical adenitis and otitis media ; the causal organism is usually the streptococcus, although the staphylococcus and pneumococcus are sometimes found. Acute nephritis, moreover, is very common after scarlet fever and diphtheria, conditions in which infection of the throat is one of the most prominent symptoms.

2. I have tried to show in this article that in the vast majority of cases of nephritis of various types it is possible to demonstrate well-marked infection of the tonsils, antra, teeth, &c. ; this is particularly the case in subacute nephritis with much œdema, and it is in these patients too that early removal of focal sepsis appears to give the best results.

3. If the kidneys are badly damaged by the long-continued excretion of a more or less virulent toxin, a surgical operation, by removing the source of the latter, may tend to slow down the progress of the disease ; but the best results are obtained when the tonsillar or other infection has been searched for and eradicated at a very early stage.

4. In the very chronic cases of nephritis with high blood pressure—200 mm. of mercury or more—even if infection is discovered, it is questionable whether the benefit obtained is sufficient to justify the risk of surgical interference. One of the above patients with a blood pressure of 210/110 mm. of Hg took a general anæsthetic well during tonsillectomy, but two months later, when having some teeth extracted, collapsed during gas.

5. It is suggested that specialist examination of the tonsils and antra be undertaken at the earliest moment in all cases of pregnancy in which albumin in the urine or other signs of nephritis appear, also in post-scarlatina, diphtheria, and other conditions in which residual tonsillar or associated infections tend to occur. Moreover, if focal sepsis is discovered it should be removed at once, as a precaution against the possibility of subacute or chronic nephritis later.

I am greatly indebted to Prof. F. Langmead for suggestions in regard to the relationship of focal sepsis to nephritis.

THE MENOPAUSAL AGE AND MAMMARY CARCINOMA

BY E. K. DAWSON, M.B. EDIN.,

FULL-TIME RESEARCH WORKER, BRITISH EMPIRE CANCER CAMPAIGN.

(From the Laboratory of the Royal College of Physicians, Edinburgh.)

MUCH experimental work has been done in an attempt to define the relation of normal mammary growth and functional activity to the influence of ovarian and other growth factors. In the human subject, histological and clinical evidence show this interdependence at all stages of the mammary life-cycle, from the initial formation of the organ before birth, through the growth activity of puberty, pregnancy, and lactation, and at the period when atrophy of glandular structure is associated with the subsidence of the reproductive function. But when abnormal growth or tumour formation, and especially carcinoma of the breast, is in question, curiously little attempt has apparently been made to correlate such pathological activity in the mamma with disordered function of the growth stimuli which produce and maintain its normal condition. Most experimental work has been an effort to establish some connexion between tumour growth and more or less extraneous factors, such as inflammatory and irritative processes, stasis of secretory or other products, and like conditions.

It is, of course, obvious that much difficulty lies in the way of estimating such correlation in the human subject, but it seems possible that more progress might be made in elucidating and defining the factors which lead to the development of tumours in the breast, if these growths were regarded, not merely as surgical emergencies needing appropriate local treatment, but as manifestations of a wider derangement in the organism. If this were so, the pathologist and the statistician might be provided with data which would assist in histological interpretation, and which would go towards building up simple but important physiological generalisations on the inter-relations of the commencement, continuance, and cessation of activity of glandular organs. It would be helpful in the attainment of this object to have on record the marriage state, the number of children, if any, whether they were nursed, any further details of the lactation history, and the length of time which had elapsed since the last lactation. These latter questions have an obvious bearing on the possibility of retention of secretion in the glandular tissue, and the part this may play in the production of benign or malignant growths. Even more helpful would be information with regard to gynæcological function and, if the patient is older, the age of the menopause and any disturbance associated with it. The absence of information with regard to these last questions is almost general, and is the more surprising when it is remembered that all statistics of the age range of malignant development in the breast associate the emergence of mammary carcinoma, in the great majority of cases, with the menopausal or post-menopausal period.

AN INVESTIGATION OF AGE-INCIDENCE.

During a study of normal mammary histology, in association with the late Prof. Lorrain Smith, the idea of trying to connect more definitely the menopausal period with pathological growth in the mamma suggested an investigation into a number of histories which might provide some more exact information regarding the age range of the menopause in women. The collection of these statistical data had in view the determination of (1) the frequency distribution of the menopausal ages, and (2) the correspondence of this with the ages at which mammary cancer makes its appearance. In the latter case, the age-period is known to be more or less coincident with that of the menopause. There is, however, in the first place, insufficient knowledge of what the age at the menopause may be, and in the second place, it would be of some interest to show how far cancer in an organ such as the mamma, with its close hormonic connexion with ovarian and uterine activity, runs parallel in regard to age-incidence with that of the menopause.

The investigation was carried out on the surgical side of a women's hospital, where gynæcological data are taken as a routine part of the patient's history. The age of the menopause was therefore available in almost all cases where the period had been completed. The conditions for which patients had entered hospital included the usual wide range of surgical lesions, with a preponderance of gynæcological disorders. A series of 300 histories of patients past the menopause was studied, but 56 cases of intermenstrual hæmorrhage and other uterine disturbances which made the time of the menopause uncertain have been excluded. This left 244 cases, a small number of the total available, but one considered sufficient for a preliminary statistical survey and for comparison with a series of malignant breast cases, which numbered 343.

The figures for the two series are as follows: those belonging to the first series of 244 cases, in which the year of the menopause was under examination, are entered in the second column (Mnp.); those of the series of 343 malignant breast cases, giving age at time of operation, are entered in the third column (Mlg.).

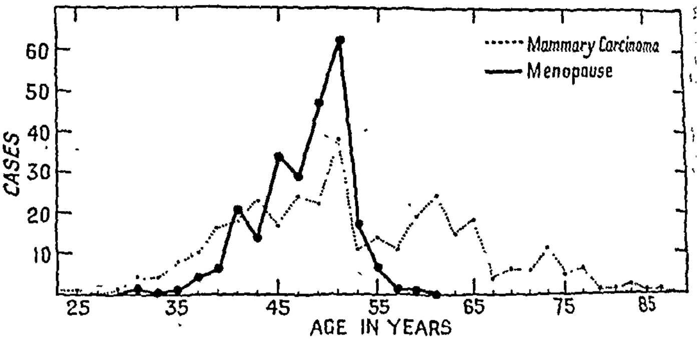
Age.	Mnp.	Mlg.	Age.	Mnp.	Mlg.	Age.	Mnp.	Mlg.	Age.	Mnp.	Mlg.
23	0	1	39	4	10	55	1	7	71	0	0
24	0	0	40	14	12	56	1	6	72	0	6
25	0	1	41	7	6	57	0	5	73	0	5
26	0	0	42	7	9	58	0	12	74	0	4
27	0	0	43	7	14	59	1	7	75	0	1
28	0	1	44	14	7	60	0	14	76	0	5
29	0	0	45	20	10	61	0	10	77	0	1
30	0	2	46	13	12	62	0	7	78	0	1
31	1	2	47	16	12	63	0	8	79	0	0
32	0	3	48	24	19	64	0	9	80	0	1
33	0	1	49	23	13	65	0	9	81	0	0
34	0	0	50	52	30	66	0	3	82	0	2
35	1	8	51	10	8	67	0	1	83	0	0
36	2	5	52	10	7	68	0	4	84	0	1
37	2	5	53	7	4	69	0	2	85	0	0
38	2	6	54	5	7	70	0	6	86	0	1

The graphs of these figures are here illustrated, the numbers being grouped in two-year periods; thus the age-period extending from the completion of the thirtieth year of age to the completion of the thirty-second year is called on the graph 31 years. However grouped—in two-year, three-year, or five-year periods—the maximum incidence, both of the completed menopause and of the emergence of malignancy in the breast, lies in the five-year period, 48 to 52 years inclusive, with the peaks close together and on the same ordinate. The wide range of the menopause—29 years—is to be noted.

WIDE RANGE OF THE MENOPAUSE.

Several facts emerge from a study of the histories which provided the menopausal figures.

1. The usual period given for the completion of the menopause is between 40 and 50 years, with the maximum incidence between 45 and 48 years, but a wider range of variation in the age—from 30 to 59 years—is brought out by these figures. This result suggests that, in the absence of detailed data, the conclusions to be drawn regarding the histological appearances in the breast, the relation of cancer to involution at the menopause and so on, should be strictly qualified. The actual age of a patient may be less accurate than the age of the menopause, as an index of mammary atrophy. It is frequently stated in the literature, for example, that cystic disease of the breast occurs, in the majority of cases, *at too early an age to be associated with meno*pausal disturbance, but in the light of these figures such a statement has little validity unless menopausal data are also available.



The age-incidence of mammary carcinoma and the menopause.

2. The earliest age in the series at which the menopause was completed is 31 years. This patient, aged 56, came to hospital with intestinal carcinoma. *She had two children, the younger aged 25.* Since the birth of this child, when the patient was aged 31, she had never menstruated again. The birth was normal, and as she was otherwise quite well, she thought it unnecessary to seek advice. I have come across a number of references in the literature to the occurrence of the menopause before 35 years; Bloodgood[1] mentions a case, also at 31 years, in a nullipara, and associates such early atrophy with absence of pregnancy and lactation. The patient with the menopause at 59 years, the latest in the series under review, came into hospital for a prolapse of 12 years' duration. She had had ten children, and a miscarriage when she was 54 years old. An extraordinary case of prolongation of menstrual life reported recently by Andrew,[2] may be mentioned here. One of his patients, an old lady of 80 years of age, "first started to menstruate at the age of 1 She is married, and has had *eleven living* children, three stillborn, and four miscarriages. Her last was born when she was 46 years of age. Since then she has been absolutely regular . . . up to about five years ago." The periods were still quite regular (at the age of 80) *though diminishing in duration.*

3. The menstrual irregularity which precedes the completion of the menopause in the series *extends* from a few months to five years; *from one to three* years is not unusual. This is not in accord with the observation frequently met with in the literature that the climacteric in women, in contrast with the

imilar period in men, supervenes more or less rapidly. Valker,[3] for example, states that "in the case of roman, the ovaries pass from full activity to complete cessation of function in the course of a few nonths; in man, the process of genital extinction nay be spread over several years." The duration f this menstrual irregularity associated with subsidence of ovarian activity suggests that the process f involution in the breast may also, in certain ases, be uneven, variable, and protracted. This possible instability or "physiological unrest"[4] may have a bearing on mammary pathology, especially when it is remembered that the majority of cases of carcinoma emerge at the same age-period as that of the completed menopause. It would be interesting to have a frequency distribution of the duration of the menopause.

4. It is often stated that the menopause is earlier f lactation hypertrophy has not taken place; various generalisations are also made regarding the association of pathological growth in the breast with such conditions as the absence of pregnancy, the absence of lactation or its curtailment, and the rapidity of successive pregnancies; but it appears from the histories in this small series of 244 cases that such statements need more investigation before they can be accepted. So far, no obvious relation is revealed by these cases between (*a*) the number of pregnancies and the age of the menopause; (*b*) the absence of pregnancy and an early menopause; (*c*) the age of puberty and the age of the menopause; and (*d*) the interval between the last pregnancy and the age of the menopause. The establishment or denial of any correlation between these data needs the examination of a larger series of cases, and these, it is hoped, will be available for a later investigation.

CONCLUSION.

In this short study I have endeavoured to make a simple survey of the duration of the menopause, and have set up in parallel the frequency distributions of the menopause and the age-incidence of cancer of the breast. I may be permitted to conclude from my figures that—

(1) The age-distribution of the menopause, as shown in this series of cases, has a longer range and frequency than is commonly allowed.

(2) The figures representing the age-distributions of the menopause and the incidence of cancer of the breast are not inconsistent with the hypothesis, suggested also by other considerations, that a correlation exists.

My acknowledgments are due to the British Empire Cancer Campaign, with whose assistance I am engaged on a general investigation on mammary carcinoma, and to the honorary surgical staff of the Bruntsfield Hospital for Women and Children, Edinburgh, for access to their case records.

ENLARGEMENT OF GOSPORT WAR MEMORIAL HOSPITAL.—Mr. A. M. Williams, county director of the British Red Cross Society, recently opened considerable extensions of this hospital. They include a new wing, bringing the number of beds up to 42, with two sun wards, a new outpatients' department, a greatly improved and enlarged X ray department, and additional domestic accommodation. The night nurses' bedrooms have been made soundproof.

Clinical and Laboratory Notes

PULSATING EXOPHTHALMOS DUE TO SPHENOIDAL SINUS MUCOCELE

BY HERBERT VINCENT O'SHEA, M.D., M.CH. N.U.I., D.L.O.,

CONSULTING EAR, NOSE, AND THROAT SURGEON TO ST. ANTHONY'S HOSPITAL, CHEAM; ASSISTANT SURGEON, METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

ABOUT two years ago a man, aged 32, was referred to me for treatment.

History.—In 1922 he had noticed bulging of his left eye, which got gradually worse, but no doctor was consulted until 1925. His medical adviser then sent him to hospital, where—according to his statement—he was radiographed and a Wassermann test was made, both with negative results. An orbital tumour was diagnosed and he was asked to attend hospital so that he could be kept under observation, but he failed to do so.

There was no impairment of vision until 1928, when the sight began to grow dim and the eye to protrude considerably. A dull pain was experienced over the left frontal region. Suddenly one day there was a profuse discharge of about an egg-cupful of thick, brownish fluid from the left nostril; this lasted about half an hour, and was followed by a certain amount of relief; the eyeball receded considerably, and the sight improved. The next day he saw his oculist, who recommended another X ray photograph. This suggested disease of the left ethmoidal region, but unfortunately only an antero-posterior picture was taken. Under an anæsthetic a large quantity of fluid, like that which came from the nose, was aspirated by plunging a long needle through the inner conjunctival fornix. This fluid was examined microscopically but revealed nothing of note. After this treatment the eye condition remained stationary for a short time, and then gradually the aforementioned symptoms and proptosis began to get worse. The patient became alarmed about the sight of his eye. It was in 1930, just 12 months later, that he was referred to me.

Condition on Examination in January, 1930.—The left eye was pushed forwards, downwards, and outwards, and was very tense; there was no narrowing of the palpebral fissure, or any signs of swelling beneath the supra-orbital margin. The eye symptoms complained of were practically nil, with the exception of slight dimness of vision. There was no diplopia. Examination of the nose revealed nothing very much except that the mucous membrane over the outer wall of the left nostril (the affected side) seemed rather atrophi

I made a diagnosis of mucocele of a posterior orbito-ethmoidal cell or sphenoidal sinus for the following reasons: (1) long history; (2) absence of any inflammatory symptoms or signs; (3) the very great extent to which the eyeball was pushed forwards, together with the absence of any swelling in the supra-orbital region; (4) the slight dimness of vision, which could be caused by pressure on or stretching of the optic nerve; (5) the previous discharge of thick, brown, viscid fluid from the left nostril.

I decided to explore the ethmoidal and sphenoidal regions endonasally.

First Operation.—Without the slightest resistance the punch forceps went through the anterior and posterior ethmoidal cells, and it was only when the sphenoidal sinus was reached that a small quantity of thick, brown fluid, such as one sees in a mucocele, was found. I did not find anything like the amount I expected, and I did not feel satisfied with the result of the operation. There was a slight discharge for 10 or 12 days, and for a time there was some slight amelioration of the symptoms.

In May, 1931, I saw the patient again and he was very much worse. The eye was proptosed to an alarming extent and he could not quite close the lids. The dimness of vision was slightly more pronounced, and a dull pain in the occipital region was felt, especially on moving the head quickly. Distinct pulsation was felt in the eyeball, though it was not visible. The patient felt rather nervy, and the condition was evidently beginning to tell on his general health. An external operation was the only thing, and I decided on this at once.

Second Operation.—I made an incision starting from the inner part of the supra-orbital margin, down the side of the nose, and continued into the vestibule. With a bone-cutting forceps I then removed part of the nasal bone and frontal process of the superior maxilla opening the floor of the frontal sinus. I then proceeded to remove the inner wall of the orbital cavity from before backwards, having first separated the mucous membrane of the outer wall of the nose from the bone so as to lessen the hæmorrhage. I had to be very careful of the structures in the orbital cavity, and I was particularly frightened of damaging the optic nerve which I knew must be stretched and attenuated.

Nothing abnormal was encountered until I came on what I believed might be the optic nerve, and then, without any warning, a column of dark reddish-brown glairy fluid shot right out of the back of the orbital cavity. The first impression one got was that an aneurysm had been opened. The pulsation was very marked, and the fluid filled the entire operation area. After several minutes of diligent swabbing the roof of the left sphenoidal cavity and posterior part of the orbit were found to have been absorbed and a large portion of the dura exposed. The contents of the mucocele had spread into the posterior part of the orbital cavity, and evidently passed backwards beneath the dura at the base of the brain. This extensive exposure of the dura, together with the fact that the large vessels and cavernous sinus were in close proximity to the mucocele, accounted for the abnormal pulsation. Working in such a dangerous area, I did not explore or do more than was absolutely necessary as soon as I was sure that I had ensured adequate drainage. I packed the entire cavity with iodoform gauze, bringing the end through the anterior nares, and stitched up the external incision with the exception of the inner angle of the eye, where I put a thin rubber tube to drain that area, the other end protruding at the nostril.

Course of Case after Operation.—After 24 hours I removed the gauze packing and washed out the nose twice daily with alkaline lotion. I put the patient on urotropine grs. 10 thrice daily for the first ten days. On the third day the temperature began to rise, and with slight remissions remained about 103° F. for seven days. The discharge was scanty; there was a fair amount of headache and dimness of vision became rather more pronounced. As was to be expected, there was considerable œdema of the left eyelid, which was entirely closed for several days. About the sixth day a large clot was removed by syringing from the operation area, through the nose; the discharge became more abundant, containing a large proportion of pus. The temperature began to drop, headache disappeared, and orbital swelling and œdema diminished. The vision, though still hazy, improved considerably. I removed the tube from the frontal region as soon as the discharge ceased, which was about the ninth day, and the external incision healed rapidly.

I saw the patient at intervals of a month afterwards, the proptosis getting less each time. The last time I saw him he was feeling quite well, back at his work, and the eye was almost normal in position. His sight had practically recovered, though he was wearing glasses on the advice of his oculist.

COMMENT.

The diagnosis of sphenoidal sinus mucocele presents some difficulty since, owing to the deep position and varied anatomical structure and size of the sinus cavity, the disease may lie latent for several years. Should any part of the bony walls be destroyed, the implication of important nerves and vascular structures makes the diagnosis still harder. The extensive absorption of bone in the case described above, and the considerable area of dura exposed, together with the close proximity to the large vessels and sinuses, gave the feeling of pulsation to the proptosed eye. A pulsating exophthalmos is usually due to an aneurysm but in this case the character of the pulsation, the long history of the case, and the absence of any marked symptoms such as headache, pain, and ocular symptoms, coupled with the previous discharge of fluid from the nose and the radiographic findings, made the diagnosis of mucocele certain.

The dimness of vision was due to the fact that the mucocele had invaded the posterior part of the orbital cavity, and not only caused pressure on the optic nerve, but stretched it considerably by pushing the eyeball forward. It was surprising that the sight was not irreparably damaged, considering the extreme proptosis and the large amount of fluid present, with the extensive absorption of bone.

While mucoceles are common enough in the ethmoidal cells, they are very rarely found in the sphenoidal sinus. StClair Thomson, in his text-book on diseases of the nose and throat, says that one case was reported by Hajek, of Vienna, while other standard text-books on the subject do not even mention the condition.

I wish to thank Dr. Margaret Dobson and Mr. Graydon Hume, both of whom first saw the case and then referred the patient to me for treatment. I am also indebted to Mr. Buckland Jones, who kindly assisted me at the second operation.

ELECTROCARDIOGRAMS OF TWO PATIENTS DURING ATTACKS OF ANGINA PECTORIS

BY DONALD HALL, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

THESE two cases confirm the findings of Parkinson and Bedford in their paper in THE LANCET of Jan. 3rd, 1931.

CASE 1.—A man, aged 72, gave a history of chest pain on exertion for some seven years. An interesting feature was that frequently he could walk quite well in the morning but could not take exercise in the afternoon without producing the pain. There was a long history of indigestion, he had a mouthful of septic teeth, and was himself insistent that his pain had no relation to his heart but was dyspeptic in origin. He was seen on Nov. 6th, 1931, in consultation with Dr. Greville B. Tait, of Handcross.

On my arrival the patient had an attack of pain radiating down both arms, and the first electrocardiogram was taken while this pain was at its height. There is contralateral RS–T deviation in leads I. and III., downward distortion in lead I. and upward in lead III. In addition, rhythm is interrupted by premature beats of auricular origin. The patient was given trinitrin, and the second electrocardiogram was taken half an hour later when he was free from pain. In it the RS–T deviation has practically disappeared, rhythm is uninterrupted, and the complexes are of lower voltage than in the electrocardiogram taken during the anginal attack. A curious feature is that what little distortion is evident in lead II. in the first electrocardiogram (Fig. 1) resembles that of lead I., while in the second (Fig. 2) the distortion follows that of lead III. This patient had clinical evidence of organic disease in raised blood pressure, enlargement of the heart to the left, and albuminuria, but as he himself was bstinate in refusing to ccept the cardiac ex- lanation of this pain it as fortunate that we ere able to obtain con- rmation of the clinical iagnosis by the oppor- nity of electrocardio- raphing him during an ctual attack.

FIG. 1.

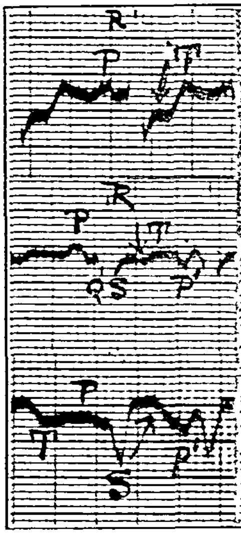

FIG. 2.

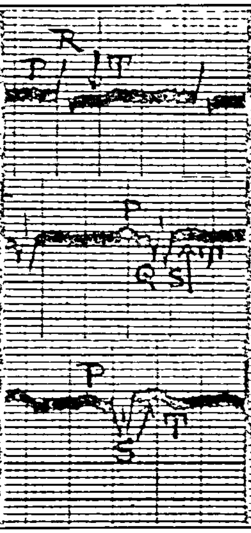

FIG. 3.

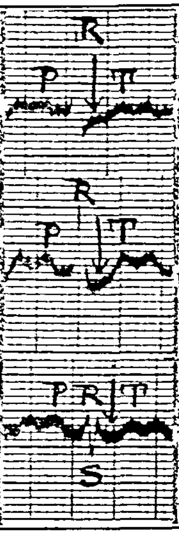

FIG. 4.

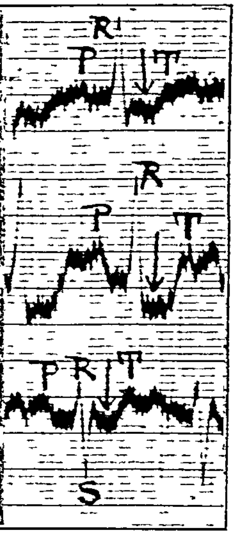

FIG. 1 (Case 1).—Taken during anginal attack. R–T depression in lead I. S–T elevation in lead III. Rate 96. Rhythm interrupted by ectopic beats of auricular origin.

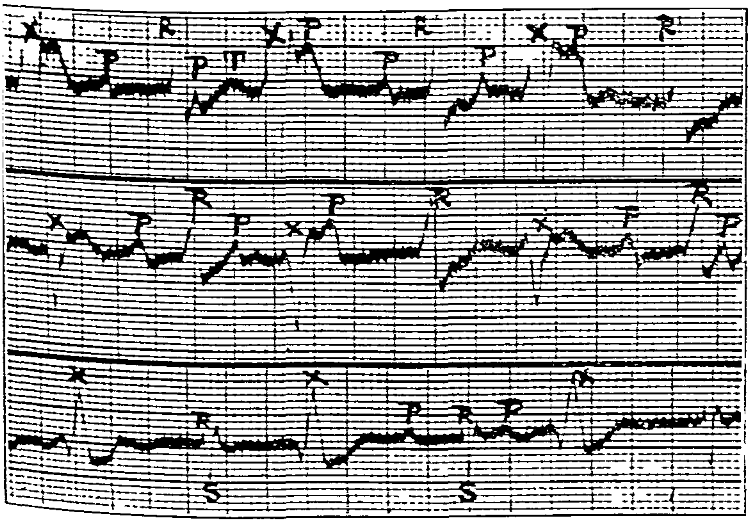
FIG. 2 (Case 1).—Taken half an hour after anginal attack. RS–T distortion much less, rhythm uninterrupted, voltage of RS waves lowered.

FIG. 3 (Case 2).—Taken during anginal attack. R–T depression in all leads. Rhythm regular. Rate 120.

FIG. 4 (Case 2).—Taken during anginal attack with very severe pain. R–T depression deeper than on previous occasion and RS waves of higher voltage.

CASE 2 was a man of 7 who was sent to ie on Dec. 8th. 1931, y Dr. H. A. Whyte- enables, of Pulborough. wo years previously e had had a "nervous reakdown." and since hat time had suffered reatly from flatulence. ll his teeth had been xtracted, and he had ad various treatments. ll without benefit, the act being that he as a confirmed wind- swallower. Thirty ears earlier he had een told that he had eart trouble, and in larch, 1918, he had een put in Category C3, and told that he had murmur. There was a history of chest pain for ver a year, the pain being referred over a ide area and, when severe, radiating down the rms, but although in the main it was provoked y exertion, such as walking uphill and kick-starting is motor-bicycle, he had been able to carry on with is employment as an insurance agent. When I saw im his eructations were loud enough to be heard

FIG. 5.



CASE 2.—Taken in terminal stage of illness. × × × = Right ventricular ectopic beats.

in the street. He had a short apical systolic murmur, not conducted outwards, and the apex was in the fifth space, only 4 inches from the midsternal line. His blood pressure was 166/90. Over the aortic area there was a very loud and harsh systolic murmur conducted upwards into the neck and heard over a wide area but not accompanied by thrill. While I was electrocardiographing him he informed me that he had his pain at the time.

The electrocardiogram (Fig. 3) shows RS-T distortion with the deflection downwards in all three leads. Later, during my clinical examination, pain returned, and on this occasion he stated that it was much worse, worse indeed than he had ever known it. At the same time he was voluble, his colour did not change, and there was nothing about him to denote suffering. I took the opportunity of obtaining a second electrocardiogram during this attack. The curve is of the same type but with extreme exaggeration of the distortion (Fig. 4).

I saw this patient again on March 23rd. His progress had been steadily downwards, and on March 10th he had a severe attack of pain lasting 36 hours with collapse, vomiting, fall in blood pressure, and subsequent pyrexia. When seen he was orthopnœic, and that morning had had hæmoptysis for the first time, evidently from an infarction of the left lower lobe. The cardiac rhythm was interrupted by premature beats, and an electrocardiogram (Fig. 5) taken at the time showed every alternate beat to originate in an ectopic focus in the right ventricle and complete dissociation of auricles and ventricles. He died on March 27th.

Neither of these patients had been taking digitalis or any drug of the digitalis group.

MEDICAL SOCIETIES

EDINBURGH OBSTETRICAL SOCIETY

A MEETING of this society was held on May 11th, with Dr. JAMES YOUNG, the President, in the chair.

Salpingitis

The PRESIDENT and Dr. T. N. MACGREGOR read a paper on the Palliative Treatment of Salpingitis based upon an analysis of 55 consecutive hospital cases. They stated that it was now generally recognised that immediate operation in cases of salpingitis exhibiting acute symptoms was attended by grave risk to life. At the British Congress of Obstetrics and Gynæcology at Manchester in 1927 Hendry reported 24 operations on acute and subacute cases (gonorrhœal and septic) with nine deaths, and Beckwith Whitehouse stated he had lost three consecutive cases when he removed the tubes for acute pyosalpinx. The last occasion on which Dr. Young and Dr. MacGregor had removed an acute tube was in 1924; the patient died two days after operation. Since then all their cases had been treated palliatively with no hospital mortality. In the present series of 55 cases 51 were admitted with acute or subacute symptoms. In three cases the abdomen was opened to eliminate the possibility of acute appendicitis or tubal pregnancy and as acute inflammation of the tubes was found the abdomen was closed without interference with the inflamed area. In four other cases a pelvic abscess was evacuated by posterior colpotomy. Otherwise the treatment was palliative, consisting of rest in bed, hot fomentations to the abdomen, and morphia. In 10 out of the 51 cases readmission for recrudescence of the symptoms was necessary, and in two of these extirpation of chronically diseased organs was later carried out. Of those cases treated palliatively which were followed up 90 per cent. were found to have made a complete or adequate spontaneous clinical recovery. These findings confirmed the observations of Curtis and Hendry who in cases of acute salpingitis treated entirely on palliative lines obtained a clinical recovery in 90 and 91 per cent. respectively.

Dr. Young and Dr. MacGregor pointed out that expectant treatment, besides safeguarding life, as a rule gave the best chance of functional recovery, since operation during the acute phase usually revealed such extensive involvement of the pelvis that eradication was possible only by drastic excision of the organs. By expectancy the organs were conserved and on these, if necessary, plastic surgery could at a later date exercise its ingenuity if pregnancy was desired. In this connexion it was important to find that functional recovery occurred spontaneously in a number of cases. In five, or 12·8 per cent., of their series there was a pregnancy after discharge from hospital.

Dr. FARQUHAR MURRAY (Newcastle-upon-Tyne) read a paper in which he discussed the insufflation test and considered that it should be made in every case of sterility, especially if there was an antecedent history of pelvic inflammation. He considered it was important to insufflate while performing a salpingostomy, not only to prove patency but by dilating the tube to facilitate the incision. Proof of patency of one tube made a laparotomy unnecessary. The test was reliable but not infallible. The occasional fallacies were shown by X ray examination after injecting lipiodol. There was a definite risk of
peritoneal shock and air embolism, but little, if an
of lighting up a septic process in the tubes or pe
toneum. Insufflation gave no clue to the site
blockage in cases with sealed tubes. Both t
insufflation test and the injection with lipiodol shou
be performed under anæsthesia.

Radiography after injection of lipiodol show
exactly the site of blockage in cases with sealed tub
If this was at the abdominal end of the tube the c
was ideal for salpingostomy, but if it was at
interstitial or isthmic portions of the tube tl
operation was inadvisable. Injections of lipio
were of diagnostic, prognostic, and therapeutic va
in cases of chronic pelvic pain. This applied especia
to those cases with no palpable evidence of tu
mischief. The injection often made the pain worse
a period and in a certain number the X ray exami
tion showed that the injection did not enter the tu
or having entered failed to reach the peritoneal cavi
or a second photograph taken 24 hours later show
that lipiodol was held up in a loculus in the tu
In a normal case there was no definition of shadov
merely a diffuse pelvic blurring at the second exami
tion. The prognostic value consisted in pr
that there was a tubal disorder in cases which w
being treated symptomatically for chronic pel
pain and in deciding which of those cases should
should not be operated upon. If proof was obtai
by X ray examination that there was drain
both into the uterus and into the peritoneal cav
then operation should be postponed; evidence
defective drainage on the other hand would has
operative treatment.

In one of Dr. Murray's cases the lipiodol inject
caused an acute attack of inflammation with
formation, but the operative findings showed
existing chronic infection. He considered that
cases requiring active disinfection under anæsth
for cervicitis and vaginitis should be injected v
lipiodol and radiographed; the pain associated v
a cervicitis was due in his opinion to a mild tu
infection, and an injection with lipiodol had a di
nostic and therapeutic value in such cases.

ROYAL ACADEMY OF MEDICINE I IRELAND

SECTION OF SURGERY

AT a recent meeting of this section with Mr.
ATKINSON STONEY, the President, in the ch
Mr. F. J. MORRIN reported the case of a wom
aged 33, who had a painless tumour in the left hy
chondrium, with all the clinical characteristics of
enlarged spleen. The blood picture excluded sple
anæmia, and a pyelogram showed a normal re
pelvis.

Hepatosplenography

Thorotrast was employed to demonstrate ra
graphically the liver and spleen. This substan
said Mr. Morrin, was a 25 per cent. colloidal solut
of thorium dioxide, stable and non-toxic, and
intravenous injection it was deposited in the retic
endothelial cells of the body. Because the liver
spleen were specially rich in these cells, the drug
deposited in sufficient concentration to render th
organs opaque.[1] Concentration of the salt
slow and its excretion was even slower. Radiogra—

---

[1] See THE LANCET, 1931, ., 144.

aken 48 hours after the injection of the full dose red the liver and spleen clearly outlined, and ther radiogram taken ten days after administering drug showed clear delineation of these organs.

was recommended that a small dose of 10 c.cm. iven in the morning and if there was no reaction sea or vomiting) a further dose of 15 c.cm. ht be given on the same evening. The necessary was from 50 to 75 c.cm., given intravenously ng three to five days. The method should not be loyed in cases of advanced hepatic cirrhosis, ite fibrosis, advanced parenchymatous involve- t of the liver and spleen, advanced jaundice, or l deficiency. It might nevertheless be useful in differential diagnosis of obscure abdominal ours.

epatosplenography in this case showed a normal liver spleen. A bismuth enema was arrested at a point just l to the splenic flexure. Operation revealed a large rculoma of the transverse colon involving the splenic ıre. A resection of the tumour was performed, and the ation completed by a lateral anastomosis of the bowel. post-operative course was uneventful.

he President thought the case very interesting, ause although tuberculoma of the cæcum was fairly mon, the diagnosis between it and carcinoma sometimes extremely difficult, and tuberculoma ther parts of the intestine was very rare. In this hepatosplenography made it clear that one not dealing with an abnormal spleen. But l more experience had been gained, he personally ld be slightly diffident about using it in all cases.

r. G. C. Dockeray said that it was supposed t antibodies were formed by the reticulo-endothelial em. Having regard to this fact, he wondered ther it might not be unwise to block the reticulo- othelial system with thorium in patients who were y ill.

r. H. Bouchier-Hayes asked if thorium had been d in cases of subphrenic abscess, and if anything known about the work which had been done with rium in cases of glandular enlargement in malig- t disease.

Ir. Morrin, in reply, said he thought that in ients who were very ill the method should not be d. He thought it probably would help in the gnosis of subphrenic abscess, but he had never d it in such a case. He had no experience of use in malignant disease.

SECTION OF PATHOLOGY

A meeting of this section was held on May 6th, h Dr. J. T. Wigham, the President, in the chair.

Ganglioneuroma

Dr. W. Boxwell showed a specimen of ganglio- uroma.

The patient, a man aged 30, was admitted to hospital have a pleural effusion tapped. He stated that before mission four or five people had tried to tap it without cess. He was very much wasted, had a history of cough many years, and had recently had bronchitis with fuse expectoration. The condition was thought to be thisical. While in hospital he had a bad cough, much pectoration, and sweating. The only place where any eath sounds could be heard was right at the base of his ng. Having regard to this fact, it was thought probable at there was not a pleural effusion. Three days after mission the patient died. Evidence of chronic bronchitis d bronchiectasis was found post mortem, with patches of eumonia, and it was thought that the patient had really ed of sepsis. The tumour, which weighed just over three unds, was adherent to a tiny little piece of lung. There s practically no lung on the right side, as it had apparently en absorbed while the tumour was growing.

Ganglioneuromata, said Dr. Boxwell, were very rare, for only 51 had been described. Most of them were quite small, about the size of a hazel-nut. They were supposed to develop from the sympathetic ganglia or from the medullary part of the suprarenal glands.

Lymphatic Leukæmia

Dr. A. R. Parsons read notes on the case of a girl, aged 4, who was admitted to hospital with a greatly swollen and hard abdomen.

The mother said that for six months the child had been losing her colour and her appetite; she did not want to play and slept all the afternoon. Before admission she ate practically nothing, but drank a good deal. The spleen was greatly enlarged, and the liver extended down to the umbilicus. The glands in the neck however were not swollen. A blood examination showed 5 per cent. of polymorphonuclear cells, and 95 per cent. of lymphocytes. She became gradually worse and died about a week after admission. A post-mortem examination was carried out.

Dr. Wigham in demonstrating the specimens said that the liver and spleen were greatly enlarged. The kidneys had no appearance at all of kidney structure, but were just white and red masses, the red masses being hæmorrhagic areas. Both liver and kidneys showed extremely well-marked lymphoid metaplasia.

Sarcoma of the Pancreas

Dr. C. J. Shortall in a paper on sarcoma of the pancreas said that neoplasms of the gland were in general rare, and most of them were carcinoma. Sarcoma was very rare and Marxer, writing in 1925, said that up to that time round-celled sarcoma had not been described.

A man, aged 31, was admitted to St. Vincent's Hospital on Feb. 23rd, 1932, suffering from severe epigastric and loin pains. These had begun in the previous December. Vomiting was infrequent. For a time the case was treated as one of gastric ulcer. Jaundice appeared shortly before admission and gradually became more intense. Slight epigastric distension and extreme tenderness in this region with ecchymosis were noted. Blood count revealed a mild secondary anæmia and the serum gave an immediate direct positive van den Bergh reaction. Cholecystography showed a liver shadow which was denser than normal but failure of concentration of the substance in the gall-bladder. The stools were clay-coloured and contained excess of undigested fat. He died on April 8th.

Post mortem the abdomen was found to contain bile-stained fluid. To the naked eye the whole pancreas seemed to be involved in a growth which at its head compressed and occluded the common bile-duct. The liver and the other abdominal organs were deeply bile-stained and the gall-bladder was distended. Microscopically the pancreatic growth was shown to be a round-celled sarcoma with small isolated patches of normal gland substance containing acini, ducts, and islets of Langerhans. A single secondary deposit was found in the liver, another in the wall of the gall-bladder, and a number in the right lung.

Dr. Parsons said that this patient had been under his care for a month in another hospital. At that time he complained of pain in the epigastrium which he said he had had for a month. It was worse immediately after meals. He was greatly wasted, and suffered from constant retching. The presence of an ulcer in the stomach was suspected. Radiography showed nothing suggestive of any intrinsic lesion.

Dr. J. McGrath said that Ewing practically denied the existence of sarcoma of the pancreas, so the present case must be a very uncommon one. The lung condition was very interesting, and it was remarkable that it was only the right lung that was involved, the left lung being almost normal.

Mr. C. O'Leary exhibited a sacro-coccygeal tumour from a fœtus, and Dr. Parsons read notes on a case of cardiac thrombus, a case of pleurisy, and a case combining cancer of the stomach, aneurysm of the abdominal aorta, and hydronephrosis.

REVIEWS AND NOTICES OF BOOKS

Recent Advances in Pathology

By GEOFFREY HADFIELD, M.D., F.R.C.P. Lond., Professor of Pathology in the University of London; Pathologist to the Royal Free Hospital; and LAWRENCE P. GARROD, M.A., M.B., B.Ch. Camb., M.R.C.P. Lond., Bacteriologist and Lecturer in Bacteriology, late Demonstrator of Pathology, St. Bartholomew's Hospital. London: J. and A. Churchill. 1932. Pp. 392. 15*s.*

Prof. Hadfield and Dr. Garrod have succeeded in what must have been a most difficult task—"to present recently acquired knowledge of disease processes in a form useful to the student of medicine." They have accomplished it partly by the method of special pathology, that is, by taking in order the systems of the body and supplying critical accounts of new work; and partly by separate chapters devoted to matters not conveniently classified by this method.

The first seven chapters deal concisely and lucidly with modern views on such difficult subjects to compress into small compass as the reticulo-endothelial system, tissue culture, different aspects of cancer research, and certain deficiency diseases. These chapters could hardly be better; and in those dealing with the various systems we find but few and unimportant matters to criticise. In the chapter on the cardiovascular system the different forms of endocarditis and diseases of the arteries are selected for discussion. The renal changes in essential hypertension are here described and it is helpful to have these changes explained as a part of the disease as a whole. It would have been a convenience to the student had the renal changes in acute and subacute bacterial endocarditis also been included in the appropriate place. In the chapter on the respiratory system an account is given of new work on the pathogenesis of lobar pneumonia, followed by a note on psittacosis pneumonia, and sections dealing with cancer of the lung and the pneumoconioses. Diseases of the digestive system are briefly noticed, with an account of Matthew Stewart's recent work on peptic ulcers, and there follows a somewhat vague commentary on hepatic necrosis and fibrosis which omits any reference to hæmochromatosis and to the recent controversy over the ætiological significance of copper in this disease. Brief comment is made on the unsatisfactory nature of our knowledge of the pancreas, and the recent discovery of the association of tumours of islet tissue with hyperinsulinism is recorded. The subject of Bright's disease receives longer and more detailed treatment both from the point of view of functional derangement and of the morbid anatomy and histology of this condition. The recent classification of Dorothy Russell has been extensively drawn upon in the description of types although the nomenclature used by her is not adopted. In "chronic toxic nephritis with reticular fibrosis type III." (p. 307) the statement that the arteries in the boundary zone are "very prominent and pointing" is misleading. This is a type found in children and young adults and is occasionally associated with renal dwarfism; it is a notable and curious fact that cardiovascular hypertrophy is usually absent or slight in this type and the renal arteries consequently show little change. In the section devoted to the central nervous system a description of the neuroglia is followed by an account of Bailey and Cushing's classification of the gliomas. This is admirably concise, though it is not free from minor inaccuracies. For instance, it is by no means generally agreed that the microglia is an element of the reticulo-endothelial system: a rival view that it is a variety of the neuroglia proper still flourishes in central Europe. The assumption which is here perpetuated that the Cohnheim-Ribbert theory on which the classification of Bailey and Cushing is based has been generally abandoned is hardly justified, for this theory is still held by many authorities. Incidentally Bailey and Cushing have never claimed that this theory would account for all the known kinds of glioma. The statement that hæmangioblastomas are confined to the cerebellum takes no account of the cerebral examples described respectively by Walshe and Barnard in this country and by Roebat in Holland. The forms of encephalitis due to virus diseases form a later section and are admirably summarised. Diseases of the ductless glands are represented by a discussion of the different kinds of goitre and of various disturbances of the parathyroid and suprarenal bodies. Special attention is directed to the alterations in calcium metabolism and the bone diseases that accompany abnormal parathyroid activity; in the next edition recent work on adenomas of the pituitary gland will doubtless claim inclusion.

In supplying references at the ends of sections, the authors have selected those only that appear to them to contribute materially to knowledge. It is open t question whether a considerable amplification of thes lists would not be advantageous, for some references ar omitted which are of first importance to the advance student. A notable example is Turnbull's classica paper on diseases of the blood-vessels. The book i illustrated by a large number of microphotograph which maintain a high standard of excellence.

The Acute Abdomen

By C. H. FAGGE, M.S., F.R.C.S., Surgeon t Guy's Hospital. London: John Bale, Sons an Danielsson, Ltd. 1932. Pp. 92. 2*s.* 6*d.*

Mr. Fagge has succeeded in giving an admirabl outline of surgical abdominal emergencies within th limits imposed upon him by the editor of this serie of pocket monographs. It is a book for an hour o two's leisure at the fireside, and one could guess tha it was similarly written in a comfortable armchai from the author's wealth of experience in this aspec of surgery. He follows the usual practice in mos emergencies. We note with interest, however, tha he is a strong advocate of operative treatment of bleeding gastric or duodenal ulcer at the earlies possible moment, using the hæmoglobin percentag as a guide to the risk incurred. He says he has neve seen gastrostaxis in a man; this must be an unusu experience if this term is held to include oozin from very small mucosal ulcers, which are reveale only by the closest search even on the post-morte table. Another interesting opinion is that expresse on the treatment of appendicitis; Mr. Fagge recommends delay in operation when the patient is seen after the third day. On page 13 the statement is made that an appendix abscess (apparently the ordinary variety) can be opened extraperitoneally; presumably Mr. Fagge means without passing through the unaffected part of the general peritoneal cavity.

The house surgeons to whom the book is dedicated, and many other individuals, will derive both profit and pleasure from reading this manual.

Surgical Errors and Safeguards

By **MAX THOREK**, M.D., Surgeon-in-Chief, American Hospital, Chicago. London: T. B. Lippincott and Co. 1932. Pp. 696. 45*s*.

Dr. Thorek, impressed by "the disastrous effect of major surgical procedures, attempted lightly by young, or even inexperienced older surgeons" of which, he says, he still has almost daily evidence, has been moved to write this book to point out the lurking dangers of even simple operations, the mistakes which may be committed, and the precautionary measures. Each chapter discusses errors and safeguards in respect to operations in general, or to those in particular regions of the body. There is no doubt that the writer of this book has struck an original note and has performed a distinct service in calling attention to the harm which the inexperienced may cause and the errors into which they may fall. Dr. Thorek has collected much information which is not easy of access. It is also extremely interesting for any operator to read of the trials and difficulties of other surgeons and to see how they have attacked the problem of extrication and with what success they have emerged.

There is much sound advice and wise counsel in the book, but it does not quite accomplish the author's aim. It falls short because, in so many instances, the way to remedy mistakes is omitted. Thus the damage which may be done to the urethra by the unskilled use of bougies is stressed, but neither the proper method of passing them, nor even the different varieties of bougie adapted to different conditions are described. This is a sad gap. Again, the spinal-accessory nerve in the posterior triangle of the neck and the supply to the depressor labii inferioris in the submaxillary triangle are certainly liable to injury during the excision of tuberculous glands it is true, but directions could be given to a surgeon on how to avoid these accidents. Again, when removing thyroglossal cysts we are told (in bold type) to dissect, not the cyst alone, but also the prolongation into it of the remnants of the thyroglossal duct; at the same time we are warned to make sure that there is a thyroid gland present in its normal position. The subject is left thus, no hint being given that the first object cannot be attained unless a small portion of the hyoid bone be removed, or any guidance on the proper procedure—i.e., whether a dissection of the neck is recommended to determine the existence of the normal thyroid. These are just the things the novice wants to know; he has probably already heard about the possibility of the accidents themselves.

Other examples of failure in constructive teaching could be found, but the book contains much valuable teaching, especially in those branches of surgery in which the author has obviously had extensive experience, as in goitre surgery. His notes on the preparation and care of toxic cases are simple and instructive. Apparently Dr. Thorek has had to perform tracheotomy for urgent dyspnœa due to a goitre in which delivery of the gland failed to bring relief; this must be a very rare emergency. Writing of high tracheotomy in another part of the book, he says that three or four rings of the trachea should be divided. This would surely mean an unnecessarily large wound which would certainly involve the isthmus of the thyroid gland. Dr. Thorek lays it down as a rule that tonsillectomy should never be performed before the coagulation time of the blood has been found to be normal.

The book, as a whole, is entertaining and stimulating; it is original in conception, and very well produced and illustrated.

The Physical Basis of Personality

By C. R. **STOCKARD**. London: George Allen and Unwin. Pp. 320. With 74 figures. 12*s*. 6*d*.

THIS book is of interest to medical readers chiefly by reason of the author's description of his own researches into the mechanism of the production of double and other monsters and into the nature and inheritance of gigantism, dwarfism, and achondroplasia in different breeds of dogs. Partial achondroplasia is common among dogs either in their faces or their legs, or both, and his investigations into its inheritance and behaviour in crosses are important in any consideration of the human disease. The work is in progress so that it is perhaps hardly fair to complain that the descriptions are defective in anatomical and histological detail, and that few facts are cited to support the implication that the ductless glands are involved.

Mental Deficiency Practice

By F. C. **SHRUBSALL**, M.A., M.D., F.R.C.P., D.P.H., Senior Medical Officer, London County Council; and A. C. **WILLIAMS**, M.R.C.S., L.R.C.P., D.P.H., Divisional Medical Officer, London County Council. London: University of London Press. 1932. Pp. 352. 12*s*. 6*d*.

THIS book, the work of experienced examiners of defectives, is designed to set out "the steps required to effect a satisfactory disposal of any given case." Methods of diagnosis are described and the administrative procedure for the purposes of both the Education Act and the Mental Deficiency Acts is defined. The book also includes short sections on causation, pathology, and psychology which, if amplified, would entitle it to rank as a text-book. In their present form, however, their omission would have been no loss. The absence of diagrams reduces the value of the chapter on pathology; and the description of the propagation on mendelian lines of a simple unit recessive serves little purpose here, since geneticists agree that mental defect is not a unit factor. The practical notes on points relating to individual mental tests are mostly excellent though occasionally somewhat elementary. Several good performance tests are included which will be found especially useful in examining older defectives, for whom the ordinary scale of the Binet type has but limited value. The authors' belief in the use of the word-association tests for high-grade cases may not be shared by all examiners. No reference is made to the significance of children's drawings. Of especial value are the indications given for the testing of blind and deaf subjects.

The arrangement of the book tends at times to a certain amount of repetition which might have been avoided. The detailed description given of the method of filling up the official examination form of the Board of Education, while undoubtedly useful, has involved the repetition of matter already given in the chapters on general description and clinical types. Moral defect is treated with unusual brevity. The authors' view is that the main characteristic of this condition is an "all-round lack of feeling tone" and while they hint at the possible association therewith of some lack of forethought and wisdom, they do not appear to stress this element so much as do some authorities. Enough is said to make it clear that a diagnosis of moral defect is not to be made lightly, and that it is not easy to fit actual cases into a definition which, as it stands, corresponds to no psychological entity and requires to be recast.

The interesting table given comparing mental ages with chronological ages of children in London special schools suggests the question why more than 10 per cent. of these children should have a mental age within less than two years of their chronological age. It would seem as if educational attainments count for more in their selection than mental ratios. This has a bearing on the larger problem raised by the Wood Report, of the desirability of abolishing certification for educational purposes.

The section dealing with administrative procedure is excellent, and the list of specimen forms given in the Appendix unusually complete.

The Donnan Equilibria

Their Application to Chemical, Physiological, and Technical Processes. By T. R. BOLAM, M.Sc. Bristol, D.Sc. Edin., Lecturer in Chemistry in the University of Edinburgh. London: G. Bell and Sons, Ltd. 1932. Pp. 154. 9*s.*

THE Donnan equilibrium theory has always attracted the attention of physiologists and biochemists interested in the physical side of their work. The classical experiments of Loeb on the application of the Donnan membrane equilibrium theory to explain the behaviour of proteins gave another fillip to the study of biological processes from this point of view. It followed naturally that others should develop these mathematical theories in relation to various processes such as secretion and diffusion in the animal body. The principle has been applied to the study of the equilibrium of blood chiefly by American workers—notably L. J. Henderson, Van Slyke, and their colleagues. Its application to the osmotic relations of the intra-ocular fluids has been attempted by Duke Elder and others, and urinary secretion has not escaped attention. This book gives an able summary of these various activities. The work is a little topheavy with physical chemistry, and the biological applications are dismissed in a relatively short space. To those who are not familiar with the literature this work will be of much value since a useful general bibliography is given at the end.

Filterable Virus Diseases in Man

By JOSEPH FINE, M.D., B.Sc., D.P.H. Glasg., D.T.M. Liverp., Assistant to the Professor of Public Health, Edinburgh University. Edinburgh: E. and S. Livingstone. 1932. Pp. 144. 6*s.*

DR. Fine has provided a really useful outline of filtrable virus diseases and we anticipate that it will find many readers amongst medical students. His task has been by no means easy, for an elementary text-book on a rapidly growing subject is far more difficult to compile than a comprehensive treatise. The various virus diseases of man, grouped according to their mode of transmission and tissue affinities, are clearly described in successive chapters. There are two appendices, in the first of which information on human virus diseases is tabulated, whilst the second resumes our knowledge of all viruses, including the bacteriophage. The scheme of classification used can only be accepted as a provisional one; the author himself realises this and has merely adopted it to facilitate the presentation of his subject. Certain contradictory statements have found their way into the work. On p. 6, for instance, one of the characters of the yellow fever group is said to be that "the serum of convalescents is capable of protecting against an injection of infective blood," and in the next paragraph that "neither immune bodies nor viricidal properties have been demonstrated in the serum of convalescents in any members of the group." Again in Appendix I we read that in zoster and varicella complement-fixing bodies are absent from the serum of convalescents; yet on p. 63 the work of Netter and Urbain demonstrating cross complement fixation with the serum of zoster and varicella convalescents is mentioned. It is not correct to say that perivascular demyelination is a constant feature of the cerebral type of *poliomyelitis* (p. 91). But to labour these points would give a false impression; for on the whole the book is accurate and clear. Dr. Fine has made it easy for those who have not the time to seek out original papers on filtrable virus diseases or to consult large works to follow the progress made in recent times, and many will be grateful for the opportunity.

Leçons cliniques sur les maladies du sang et des organes hématopoïetiques

By CH. ACHARD, Professeur de Clinique Médicale à la Faculté de Médecine de Paris; Membre de l'Académie de Médecine et de l'Académie des Sciences. Paris: Masson et Cie. Fr. 34.

HÆMATOLOGY has proved one of the most fruitful fields of medical research during the past eight years; but this clinical note on the diseases of the blood and the hæmopoietic organs, by Prof. Achard, in which he has incorporated much recent work from different sources, should serve to check undue optimism. In only three of the conditions described does he offer any hope of recovery or of rational treatment. He does not, however, discuss the part played by deficient nutrition in the ætiology of certain anæmias, nor is mention made of idiopathic microcytic anæmia or acholuric jaundice. His conclusions might, therefore, be considered unnecessarily pessimistic. Each disease discussed is illustrated by extremely detailed case-histories together with the results of repeated blood examinations; these are sometimes difficult to follow since they are not arranged in tabular form. Unlike most observers he believes that hæmophilia may occur in women. He does not mention recent work from Chicago on the possible significance of the female sex hormone in the ætiology of the condition; this work, if confirmed, may have a bearing on treatment. A few observations by G. Fontes and I. Thivolle, published in *Le Sang* (1930, iv., 658), on the therapeutic value of the injection of tytophane and histidine, which has as yet received no corroboration, form the basis for the somewhat sweeping conclusion that lack of these two amino-acids, due to deficient gastric digestion of protein, is responsible for the failure of hæmopoiesis characteristic of pernicious anæmia. The chapters dealing with leukæmias and the confusing conditions of aleukæmic leukæmia and agranulocytosis contain many interesting clinical observations. Prof. Achard wisely insists on the danger of over-emphasis of minute morphological differences found in the white cells of the peripheral blood. Such differences depend in many instances upon a personal factor.

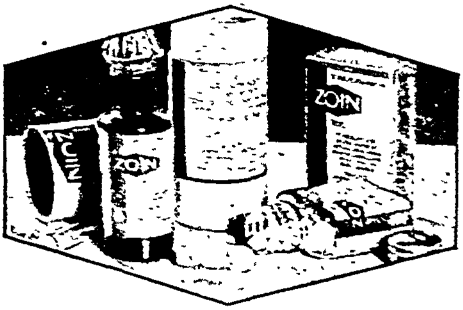
AN AMINO ACID PHOSPHORUS COMPOUND OF ANIMAL ORIGIN

PACKAGES: Tablets of 0.25 grm. (approx. 4 gr.) in bottles of 30. Liquid in bottles of 30 c.c.

DOSAGE: 1-2 tablets or 1-2 c.c. of Liquid Zoin two or three times a day. Zoin improves the appetite and should be taken before the principal meals.

ZOIN "CIBA"

is indicated in all cases in which a rational phosphorus therapy is needed. Among these are exhaustion states, especially those occurring during and after infectious diseases (tuberculosis, influenza, etc.), disorders of metabolism and of growth, anæmia, chlorosis, functional neuroses, neurasthenia, pregnancy and lactation.



THE CLAYTON ANILINE COMPANY LTD.
Pharmaceutical Department
40 Southwark Street, LONDON, S.E.1
Telephone: Hop [illegible] (3 Lines)   Telegrams: [illegible] London

For the Physician who prefers to prescribe BRITISH these products are of special interest

"Allenburys" Beef Juice

In its preparation the nutritive and stimulant constituents and the vitamins are preserved by manufacture at a low temperature and concentration away from air. "Allenburys" Beef Juice is of great value in Fatigue, Debility, Convalescence, Wasting Diseases, Digestive Disorders, and many other conditions where a concentrated, easily assimilated, fluid diet is desirable.

In patent capped bottles.

"Eulaxase"

A combination of biliary and intestinal secretions with agar agar and bacillus acidophilus, enclosed in a special coating of activated charcoal.

In bottles of 60 tablets for prescribing and 600 tablets for dispensing.

"Caloplast"

An improved poultice for the application of moist heat.

It is composed of a specially finely levigated and sterilized absorbent clay (kaolin), with which glycerin and the oils of camphor, pine, and wintergreen are evenly incorporated.

In ½ and 1 lb. tins.

"I-so-gel" Granules

A preparation of certain tropical seeds, consisting almost entirely of dried mucilage, useful in both chronic constipation and diarrhœa.

In bottles containing 5 and 10 ozs.

"Euvalerol" Elixirs

The "Euvalerol" Elixirs are prepared from fresh valerian root by a special process which, while ensuring the retention of the active principles contained in the volatile oil of valerian, eliminates the objectionable odour of the ordinary valerian products.

For Prescribing: 4 oz. and 8 oz. bottles.
For Dispensing: 40 oz. and 80 oz. bottles.

Dextrin-Maltose

A readily assimilable soluble carbohydrate mixture indicated in digestive disorders of infants, children and adults. This mixture of carbohydrates is easily digested, resists fermentation, and counteracts tendencies to diarrhœa. It makes milk more digestible. In four forms.

In 1 lb. glass jars.

Digitalin Granules, "A. & H."

A British preparation, consisting of the *Digitaline cristallisée* of the French Pharmacopœia. Its use is recommended on high authority in cases where galenical preparations of digitalis have failed.

For Prescribing: In tubes containing 40 granules
For Dispensing: In bottles containing 250 granules.

Descriptive Literature on one or more of the above products will be sent post free to members of the Medical Profession upon application.

THE LANCET.

LONDON: SATURDAY, JUNE 11, 1932.

THE PERSISTENT OFFENDER

THE report[1] of the Departmental Committee on Persistent Offenders naturally does not confine itself to the custodial aspect which the events and consequences of the Dartmoor mutiny recently emphasised. It looks to the reform of the offender before he becomes persistent. In 1930, the latest year for which criminal statistics are available, more than half the 3900 sentences of imprisonment were imposed on persons who had already been in prison. The figures confirm the conclusion that the probability of a relapse into crime increases with the number of previous sentences. The inference is that our present methods do not check the criminal propensities of the persistent offender but progressively deteriorate him. What then are we to do about him? First of all, what manner of man is he? Prison authorities group him in three categories—first, the offender of relatively strong mind and character (often young and therefore more susceptible to the reformative process) who has deliberately chosen crime; secondly, the weaker spirits who drift into crime through inability to face the difficulties of social life; and thirdly, the pathological cases of abnormal or subnormal mentality amenable possibly to medical or psychiatric treatment. To this third class and the committee's observations thereon we will presently return. Meanwhile, to run briefly through the committee's reasoned recommendations, it is proposed to abolish penal servitude and the cumbrous and already obsolescent procedure (under Part II. of the Prevention of Crime Act, 1908) for giving additional sentences to habitual criminals. The committee advocates two new forms of punishment, detention (for a period from two to four years) and prolonged detention (for a period from five to ten years). The change is partly one of vocabulary. Prolonged detention is proposed for a person convicted of a crime who has at least three previous convictions of crime and whose criminal habits and mode of life are such that lengthened confinement is expedient for protection of the public; this is not very different from the existing law. But "crime," it is proposed, shall include not only all felonies (as already in Part II. of the 1908 Act) but also certain sexual offences and all attempts to commit "crime." The latter categories are at present excluded because they are misdemeanours and not felonies—an anomalous distinction which is ripe for removal. Both classes of the new detention will aim at remedial training; there are to be carefully graded establishments suitable for all types of offender, a new impetus in adult education and industrial training, and full trial of labour camps, "minimum security structures," the parole system, and the possibility of applying female influence by the appointment of matrons in penal institutions. If penal servitude is to go, we may hope that various grim enactments as to transportation will at last be removed from the statute book where they at present linger because, by a typical Parliamentary makeshift, they were applied for the purposes of penal servitude.

Chapter XI. of the report is of much interest to medical readers, for here we find discussion of those pathological cases which are possibly amenable to psychiatry. Here the committee attempts to answer the question how far the persistent offender can be treated as a mental patient. Reviewing the statutory facilities for dealing with the habitual drunkard and the mentally deficient, the committee passes on to those types of minor mental abnormality for which no special statutory provision exists. There are the weak-minded who leave school without adequate after-care arrangements. There are the delinquents who may become persistent offenders through emotional and temperamental instability; some of these cases appear to right themselves when physiological balance is regained after adolescence. Then there are the offenders who repeatedly commit the same kind of crime, acts of indecency and other sex offences, magpie thefts, and certain minor peculations, arson and some other acts of wilful damage against property. Punitive and reformatory measures of the ordinary sort seem here ineffective; yet some mental abnormality must be the cause of this conduct which is a menace or a nuisance to society. After examining the evidence of experts in psychotherapy, the committee guardedly proposes to try what psychological medicine can do. It recommends that a medical psychologist be attached to one or more penal establishments to carry out treatment in selected cases. He should be assisted by voluntary women workers who will visit the offender's home and obtain information about his history and circumstances. Already for some time lads under 21 years of age who are received in the Boys' Prison at Wormwood Scrubs, sentenced to detention in a Borstal Institution, or remanded from the Metropolitan and adjacent areas for medical report, have been psychologically examined by the medical officers of the prison. The committee considers that extended action along these lines will show whether the psychological treatment of delinquency is of sufficient value to justify statutory recognition. At the same time the committee is careful to affirm its belief that crime is not a disease, and that it is impracticable and generally unnecessary to examine the mental condition of all adults who appear in court upon a criminal charge. The affirmation of this belief is a reminder that the Home Office is not yet ready either to abandon the legal principles of criminal responsibility in relation to abnormality of mind or to take full advantage of the help that medical science can give. The committee's recommendation, nevertheless, is a notable step which may lead legal principles far afield.

TRANSURETHRAL PROSTATECTOMY

THE two papers on prostatectomy at the front of this issue are concerned with a variety of the operation which has had little notice in this country. Indeed, apart from a paper written by Mr. KENNETH WALKER[1] in 1925, we can recall no extensive review of the modern methods of transurethral resection; and it is to be hoped that our American contributors will succeed in arousing some of the interest in it which has evidently inspired their own experiments.

The national tradition in surgery is in favour of thoroughness, and an operation which removes only part of the prostate, and leaves behind tissue that may increase in size and cause recurrence of symptoms, is apt to appear incomplete and therefore unsatisfactory. For this or other reasons most urologists here are of opinion that cases suitable for this form of treatment are few and far between. In the light of the papers by Prof. CABOT and Dr. MCCARTHY can this attitude be justified? Whatever the answer, it is clear at any rate that the whole subject of the prostate and its treatment is full of difficulty. We do not know for certain whether what we remove in "prostatectomy" is in fact the prostate, or whether it is—as some pathologists have long maintained—an enlargement of the submucous glands of the posterior urethra. Our knowledge of its physiology and pathology is indeed so far from complete that guidance in treatment must be sought in clinical results rather than in any general principles. From the standpoint of the clinician the results of prostatectomy are excellent, but it certainly has to be admitted that they are obtained at no small price, for the operation still carries with it a high mortality. This mortality is not of course surprising, in view of the age of the patients and their liability to post-operative complications; but an operation with a death-rate that ranges from 8 per cent. to 20 per cent. can hardly be regarded as satisfactory, however great and however permanent the benefit to the survivors may be. The most careful consideration must therefore be given to any form of treatment that carries a lesser risk—even if the critic starts with a reasonable suspicion that the relief it gives cannot be so lasting or so complete as that which follows more radical intervention.

It is said that the transurethral operation is appropriate in only a small proportion of cases of prostatic obstruction; but CABOT and MCCARTHY agree that recent developments have greatly extended its scope. The latter goes so far as to say that "90 per cent. of prostatic enlargements, malignant or otherwise, may be regarded as so much plastic material to be removed seriatim by a loop charged with a new type of cutting current." This is a claim that may well prove excessive, but the more conservative estimate given by Prof. CABOT is high enough to dispose of the contention that transurethral therapy can rarely be used and is therefore of little importance. CABOT, who has long been known as an enthusiastic advocate of suprapubic prostatectomy, holds that 50 per cent of cases of obstruction are amenable to treatment by transurethral methods, and he anticipates that with improvement of technique something like 75 per cent. will eventually be brought within their range. Only the patient with a massive enlargement of the lateral lobes will have to face the greater peril of complete prostatectomy, and as W. F. BRASH points out[2] this type of prostate is becoming rarer. The patient of to-day seeks medical advice at an earlier stage of his trouble, for it is now more generally known that safety lies in timely treatment. Hence the proportion of cases which could be treated by transurethral prostatectomy is greater than it was formerly, quite apart from the progress that has been made in technique. How far the present hopes may be disappointed is necessarily uncertain, but even allowing for unexpected limitations it is hard to avoid the conclusion that the operation is one which has come to stay.

ANIMAL ECOLOGY

As a natural reaction to the analytical method which has been so characteristic of biological progress in the last hundred years, we have heard a good deal in recent times of the necessity of studying the animal as a whole. Most workers whose aims and procedures are professedly scientific have found a good deal of difficulty in investigating live things without taking them to pieces; naturalists alone have been content to look at animals and plants as they are, to know about them and to be with them, and to those who are brought up in the confines of laboratories their attitude towards the organisms which interested them must have seemed as much that of a lover as of a student. We are now happily returning to the atmosphere of the eighteenth century, and are reviving a natural history which is as scientific as any other section of biology in the sense that it is orderly, systematised, and quantitative. The object of animal ecology is to discover how animals live and die, their breeding and multiplication, their food, their enemies, and the causes of their death—to find out, that is, for the blackbird, the mole, the stickleback, and the slug what the hygienist is anxious to know about man. It seems strange that in the 70 years which have passed since the publication of the "Origin of Species" so little has been done to ascertain the actual facts on which the whole theory of that book depends; that natural selection operates has been accepted, but of what it operates on and by what means, we are still largely in ignorance. It is the business of ecology to find out.

The inherent interest of the search is obvious, and its practical importance is now sufficiently plain. Man's control of his biological environment depends on his knowledge of how it lives and moves and has its being. Malaria, trypanosomiasis, plague, typhus are all in the main ecological problems. and our capacity to deal with them depends mostly on how much we know of the lives of mosquitoes, tsetse flies, fleas, and lice. The strange periodical fluctuations in the numbers of animal populations to which Mr. ELTON has paid particular attention are responsible on the one hand for the price of a fur coat and on the other for the wholesale ruin of a countryside by locusts. The student of infectious diseases wants to know what happens when the natural interaction between a parasite and its host is not interfered with by conscious sanitary measures; what exactly is the relation between the plague bacillus and the rat, or between trypanosomes and game in Africa? Are infections with bacteria, protozoa, and viruses important causes of death in natural populations of animals as they are among artificial populations of human beings? Real comparative pathology has hardly been born yet; that it will have abundant applications to human problems there can be no doubt.

---

[1] Brit. Med. Jour., 1925, i., 201.

[2] Minnesota Med., April, 1932.

For these reasons we heartily welcome the appearance of the new *Journal of Animal Ecology*, though some may wish the promoters had seen fit to use the original European spelling of the key word. It is issued[1] by the British Ecological Society which has published the *Journal of Ecology* (mostly botanical) since 1913, and is edited by Mr. CHARLES ELTON and Mr. A. D. MIDDLETON, of the department of comparative anatomy at Oxford. The first number contains a quantitative account of the rookeries in the Wirral, a census of the bird population of an Oxfordshire farm, an analysis of the fluctuations of midges infesting wheat, the prey of a carnivorous fly, and an extremely interesting description of how each nest of wood ants in a coppice has its own territory and feeding grounds. From abroad we have papers on bird life in Brazil and fruit bats in Australia. The journal should appeal to readers of very varied interests, and it will play a most useful part in the development of real biology; we hope it will quickly receive the support which it needs to put it on a sound foundation.

THE NUTRITIVE VALUE OF MARGARINE

MARGARINE is one of the foods which is not at present officially defined in this country and it can legally be made from any kind of fat. The chief restrictions regarding its composition are that it must not contain more than 16 per cent. of water nor more than 10 per cent. of butter fat. The modern manufacturer employs fats from both animal and vegetable sources and is able to produce from these a substitute for butter which may compare favourably with butter itself in regard to appearance, consistence, and taste. The Institute of Hygiene recently appointed a committee to consider the conditions which margarine should fulfil in order that it might be certified as a good food. It was agreed[2] that as sources of energy margarine and butter were equally valuable, so far as could be determined. The chief difference between the two foods is in their vitamin content. Butter is a valuable source of vitamin A and contains moderate amounts of vitamin D, whereas most brands of margarine are deficient in both of these vitamins. It is now possible to add concentrated preparations of these vitamins in a comparatively stable form to margarine during the process of manufacture, and vitaminised margarines are already being sold which contain at least as much vitamin A and vitamin D as good butter. The vitamin content of such margarines is likely to be more constant than that of butter, which is known to vary considerably with the conditions under which the cows from which the butter is derived are kept. It is the usual practice in this country to colour margarines, and for this purpose either carotene or aniline dyes are used. Carotene is now recognised as the precursor of vitamin A, and its presence in margarine enhances the vitamin A activity of the product. In view of these facts the committee have submitted certain recommendations with regard to the properties of a good margarine. The product must be made from pure ingredients and must contain vitamins A and D in amounts equivalent to those found in samples of the best summer butter. It should not contain more than 10 per cent. of water and must be free from added preservatives other than salt. It should be coloured with carotene and not with aniline dye. It was further recommended that it should contain butter fat up to the present legally permitted limit of 10 per cent. of the total fat; a limit which is fixed by law at this low level to enable the analyst to distinguish readily between margarine and adulterated butter. Such a margarine might conceivably be inferior to natural butter in nutritive value owing to the absence of food factors other than vitamins A and D from the synthetic product, but its food value would be definitely superior to that of ordinary vegetable margarines.

◆

THE BIRTHDAY HONOURS

ON page 1275 will be found the names of medical men and women who received honours on the King's Birthday. These do not, of course, represent the full recognition bestowed upon medical endeavour, for the complete Honours List contains the names of many who have worked in alliance with medicine though they do not belong to the profession. Among the new barons Mr. David Davies has given substantial help especially to the King Edward VII. Welsh National Memorial Association, of which he is now president. Mr. James Macfarlane, who receives a knighthood, is chairman of the Glasgow Royal Infirmary, and by gifts and otherwise has done much to make possible its extension at Canniesburn. Notable among the Commanders of the Order of the British Empire is Miss Margaret Anderson, lady superintendent of the East End Maternity Hospital; and elsewhere we see with pleasure the names of others who have distinguished themselves in the service of hospitals and laboratories in nursing and in public health administration.

ANNOTATIONS

LAWSON TAIT

Mr. Christopher Martin has done well to reprint the substance of two lectures which he delivered, one to the Midland Medical Society, the other to a group of American visitors. In these he gave an unbiased account of the life and work of Lawson Tait[1] and by personal reminiscence assists us to appreciate the kind of man that he was, going far to remove the wrong impressions created by Tait's foibles and failings. Lawson Tait was the pioneer of much in abdominal surgery, and started almost as a child on the road to surgical success. Born in 1845, he won a scholarship at the University of Edinburgh in 1860, and while still a student became a pupil of Sir James Young Simpson, in whose house he lived. To Simpson he bore such a remarkable resemblance that the belief that he was his patron's illegitimate son was widely held, though the rumour has been indignantly contradicted by members of Simpson's family. Despite his precocious and promising start, and his early association with Simpson, Tait did not proceed to a medical degree, but contented himself with the Edinburgh diplomas which he obtained in 1866. In the following year he was appointed resident surgeon at the Clayton Hospital, Wakefield, and in 1868 he performed his first ovariotomy with success. He stayed at Wakefield for three years and then started in general practice, but with the intent to make operative surgery his career, although he was at that time attached to no hospital and held no academic position. Real genius backed by enthusiasm and some aptitude for self-advertisement brought him practice, and by 1880 his name as an abdominal surgeon was widely familiar to all England. Mr. Martin gives a calendar of his achievements which makes astonishing reading, while the professional position that he acquired and the appointments which fell to him are remarkable, when it is recalled that from 1880 onwards Tait lost no opportunity of opposing Listerian surgery. But a summary of his own technique in abdominal surgery shows that, while he was wrong in his attacks on Lister, his extreme cleanliness was undoubtedly a forecast of modern aseptic methods. His first move was to join in the foundation of a special hospital, as he was debarred by the absence of honours degrees or diplomas from obtaining a post on the staff of a teaching institution. He sat down while in general practice to read for the F.R.C.S. Eng., and promptly secured the diploma. He then took a leading part in founding the Birmingham Medical Institute, and in 1881 read at an International Medical Congress a paper embodying five entirely new surgical procedures of the first importance. He was now appointed professor of gynæcology in the medical faculty of Queen's College, Birmingham, out of which to some extent the University of Birmingham evolved, and finally he was elected president of the Gynæcological Society and of the Medical Defence Union, which he had largely helped to reconstitute. Everything about Tait's life was dramatic, and it is a dramatic fact that a libel action of exactly the sort where the Medical Defence Union should have been able to help him started Tait's downfall, which was as rapid as his rise. The action had to be compromised owing to Tait's own conduct, and the fact damaged him greatly in the eyes of the public. His practice rapidly declined, he resigned his numerous important offices, and he died in comparative poverty at the age of 54. An enigmatic figure, but Mr. Martin brings evidence forward that proves his services to scientific surgery to have been literally wonderful.

SEROUS PLEURISY DURING THE SPECIFIC FEVERS IN CHILDHOOD

A TYPE of pleurisy associated with a very thin fluid effusion and presenting physical signs which can easily be overlooked, has long been recognised at the Wilhelmina Hospital in Vienna, and during the last year has been more closely studied. Dr. Hermann Zischinsky[1] reports that within this period 40 cases have been seen, of which 25 were associated with scarlet fever, nine with diphtheria, one with measles, and five with a double infection by scarlet fever and diphtheria. Cases have been recognised in association with whooping-cough, and Zischinsky is careful to point out that most of the patients coming to his department—the infectious fevers section of the hospital—have scarlet fever, whereas only a small number come with whooping-cough, so that he is not in a position to say which of these infections is most likely to have pleurisy as a complication. The pleurisy begins almost without symptoms save a few days' rise in temperature. Occasionally the child complained of pain in the side of the chest or, more commonly, in the abdomen. There was no dyspnœa, and cough, if any, was very slight. As a rule nothing was found on examination beyond slight impairment of the percussion note at the base of one lung, with recovery of fluid on exploratory puncture over this area. The signs were far commoner at the left base than at the right (34 left and six right in the 40 cases under review). The dullness usually only covered a few fingers' breadth but occasionally reached as high as the angle of the scapula. Auscultatory signs were usually absent, or at the most consisted of slightly diminished breath sounds over the affected area. In 30 out of the 40 cases exploratory puncture revealed fluid; usually this was quite clear or very faintly clouded and only a few drops were obtained. Examination proved it to be sterile in most cases, although once diplococci and once staphylococci were discovered. In about half the cases, a few leucocytes were found in the fluid, but as a rule no cells were seen. The duration of the pleurisy was difficult to determine with accuracy, because there were so few physical signs, but the extreme limit appeared to be five weeks, and the shortest time for the disappearance of signs after a positive pleural puncture was five days. The tuberculin reaction was tested in each case and was positive in one-third—a proportion which Zischinsky regards as about normal for a sample of the child population at the appropriate ages. He therefore thinks that the pleurisy he is describing has nothing to do with tuberculosis. Radiological examination of some of the patients was not very helpful. Negative results were sometimes obtained although exploratory puncture had been positive, and the difficulties of radiographing infectious cases made it hard to investigate this method of diagnosis fully. It is insisted that a film should always be taken, for it may reveal an exudate which was missed on screen

---

Jahrb. f. Kinderh., 1932, cxxxv., 213.

examination. The ages of the patients here described varied from 1¾ to 14 years, with the majority between 3 and 8. The day of onset in relation to the primary fever also showed great variation. For example, in the scarlet fever cases, although these were mostly seen in the first ten days of illness, the pleurisy came on at different times from the fourth to the thirty-sixth day. Zischinsky thinks that this type of pleurisy may be commoner than is usually believed, and not only among children with infectious fevers. There are other children in whom a few days of fever, associated with loss of appetite and energy, may really be due to this cause.

LIVINGSTONE HOSPITAL REPORT

AN unfortunate occurrence at the Livingstone Hospital, Dartford, when a young probationer nurse gave a patient belladonna in mistake for syrup of figs, was investigated at an inquest as noted at the time in THE LANCET (Feb. 20th, p. 418. The hospital trustees wisely invited a further inquiry, which was undertaken at their request by a committee constituted as follows: Mr. R. H. P. Orde, hon. sec. of the British Hospitals Association (chairman), associated with a medical superintendent of a hospital, a matron, a hospital secretary, a member of the hospital committee, and a barrister. The resultant report, which was unanimous, was subsequently published in the *Kent Messenger* together with a detailed statement by the president of the hospital, who was able to say that all the recommendations in the report had been promptly carried into effect. Although directed to the particular facts upon which the coroner had commented, the report of so well-equipped a committee of inquiry formulates standards of hospital management which may be found useful elsewhere. The report points out that the ultimate responsibility for efficient management of a hospital rests with the committee of management and that this responsibility is not entirely discharged by the appointment of officials, however competent or highly qualified they may be. The committee of management has a duty to provide (*a*) organisation whereby its officials may regularly present to it reports relating to their duties, and (*b*) certain safeguards of a general character whereby it can satisfy itself regarding the state of the institution for the good management of which it is responsible. Regulations, therefore, in accordance with the general practice of other similar hospitals should at once be drawn up and put into force. Hospital administration is impeded by the absence of rules defining the duties and responsibilities of the different members of the staff; this absence of rules results in lack of proper supervision and an inadequacy of essential written records and reports. Books, records, all documents, charts, and papers relative to the treatment of patients must be properly and clearly kept by the officials concerned. Essential details should be periodically abstracted from these sources and presented to the committee of management in such a fashion that it is possible for each member to obtain a grasp of the work of the institution for the management of which he shares responsibility. As regards poisonous drugs the committee of management should provide all necessary safeguards in respect of purchase, receipt, storage, dispensing, and administration. The committee should insist that in all cases there is written authority, signed by the medical officer prescribing, for all medicines and applications of any description; this authority should be definite and applicable only to the individual patient concerned. A fully qualified person should attend the hospital for a short period daily to issue all drugs. No persons other than qualified medical practitioners or chemists should have access to the dispensary. As regards nurses the committee of inquiry, sympathetically aware of the difficulties experienced by smaller hospitals in obtaining suitable probationer nurses, recommends the committee of management to essay the gradual improvement of the status of the hospital, either by increasing the number of beds, so that it may be recognised as a teaching centre, or by affiliation to an adjacent and convenient institution already serving as a training centre.

The perfect and elaborate system of hospital rules can no more eliminate the possibility of accident than the latest Merchant Shipping Acts and regulations can remove all risk of collision at sea. But it is obvious that the absence of clear rules is dangerous in hospital administration and that, if accidents unfortunately occur, such absence is bound to attract strong comment.

TRANSPLANTATION OF THE URETERS

TRANSPLANTATION of the ureters into the bowel is so rarely performed that reports on the operation are usually concerned with single cases. Hence the record therefore of five cases by F. H. Lahey [1] forms a valuable contribution. He has followed the technique introduced by Coffey, and speaks very highly of this operation, which he considers can now be done with very reasonable safety and with the assurance of a satisfactory result. Of the five patients three survived and have been followed for periods of 22 months, 9 months, and 5 weeks respectively. One died on the ninth day after operation, of lobar pneumonia, the condition of the operative site being entirely satisfactory; the fifth survived the ureteral transplantation but died a month later from an extensive operation for the removal of bladder and uterus. The indications for operation in these five cases were early carcinoma of the bladder, a contracted bladder consequent upon tuberculous cystitis, a vesico-vaginal fistula which was not cured by four plastic operations, inoperable carcinoma of the bladder, and a carcinoma involving the bladder and front wall of the uterus. As other indications for this operation, Lahey gives exstrophy of the bladder, intractable incontinence of urine, contracted bladder following Hunner's ulcer, and occasionally the relief of pain in extensive malignant disease of the bladder. Lahey transplants both ureters at one operation, but at a discussion on transplantation of the ureters for ectopia vesicæ at the Royal Academy of Medicine in Ireland,[2] most of the speakers advised transplantation of one ureter at a time. The rectum acts as a very efficient reservoir for the urine, and leakage does not take place, the bowel being emptied of urine about three to five times a day and perhaps once at night. A. A. Lendon and H. S. Newland [3] found similar satisfactory results in this respect in their cases which survived long periods of 21 and 16 years respectively. W. C. Stevenson, when opening the above-mentioned discussion, reported that his patient, a boy of 10 years, occasionally wetted the bed at night. As Lendon's patient developed symptoms of renal infection nine years after extraperitoneal implantation of the ureter into the rectum, it will be seen that it is essential to follow these cases over a long period. Lahey states that with the Coffey technique there is but little likelihood of ascending infection of the kidney.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: LEVERHULME RESEARCH SCHOLARSHIPS

As announced elsewhere, Lord Leverhulme has instituted two annual scholarships in medical research, the discretion of appointment and term of tenure being vested in the Royal College of Physicians of London. The scholarships are each of the annual value of £500, and the appointments will be for one year in the first instance, the renewals being at the discretion of the College. The scholars must be British subjects, and the work must have as its base some established institution, preferably in the United Kingdom, in which full facilities for the selected research are available. The scholars, who may be of either sex, must be not less than 25 years of age, and preferably possess a medical qualification. They must devote themselves to the investigation of some clinical problem of disease, as it occurs in man, and presents itself in any branch of medicine or surgery, while two scholars may combine in a joint research. It is to be noted, further, that scholars may be holding another appointment, or may be commencing private practice, provided that evidence is furnished to the College that the work of the research occupies the major part of their time. These latter conditions should be read in connexion with the age stipulation; it is clearly intended that the holders of these valuable prizes should have had clinical experience, and not have passed straight from the examination halls into the laboratories. The regulations state that each scholar shall send to the Registrar of the College an abstract of the work on which he has been engaged at the end of the first six months of each year, and a full report at the end of each completed year of tenure. Payment will be made in instalments, the first at the date of selection for the scholarship, and thereafter at intervals of six months. The scholars may publish the results of their researches, if they make known that the work has been done during appointment as a Leverhulme scholar.

Applications for scholarships should state: (1) name and age; (2) medical qualifications, degrees, &c., with dates; (3) past appointments, with dates; (4) present appointment, with salary (if any); (5) nature and scope of research proposed; (6) previous experience (if any) in research work; (7) list of papers published (if any), giving references; (8) place where proposed research is to be carried out; (9) names of two persons prepared to act as references. The applications should be addressed to the Registrar, Royal College of Physicians, Pall Mall East, S.W. 1, and marked "Leverhulme Scholarship." These should reach the College on or before July 4th.

MAX RUBNER

The death of Max Rubner at the age of 78 years, which was announced last week, deprives Germany and the world of one of their most distinguished men of science. More than 50 years ago, as a pupil of Voit, he began researches into the fundamental processes of metabolism which soon made his name widely known, and during his long and active life his contributions to the study of the energy exchanges of the body have been of supreme importance. He earned the title of professor at Marburg in 1885, and six years later was appointed to succeed Robert Koch as director of the Institute of Hygiene in Berlin. It was he who discovered that the basal metabolism of an individual was proportional to his surface area, and his figures for the calorific equivalents of protein, fat, and carbohydrate in the body are still widely used in calculating the energy values of diets. He demonstrated that the law of conservation of energy held good in the case of animal metabolism by perfecting the calorimetric methods of Pettenkofer and Voit. Some of the expressions which he coined have become household words in the science of nutrition, for example, "specific dynamic action" to indicate the increase of metabolism caused by the ingestion of protein, and the "wear and tear" quota of protein metabolism to describe the irreducible minimum of protein destruction in an animal supplied with abundant carbohydrate food. His work was by no means entirely academic. During the Great War he was called upon by the German Government to examine the possibility of increasing the available food-supply of the population. He carried out experiments on the digestibility of bran, and of chemically treated straw and sawdust, though without success; he remained convinced that the most economical preparation of wheat for human consumption was that in which 30 per cent. of the grain was milled away. During the last 20 years the qualitative aspects of nutrition have attracted far more attention than the quantitative aspects to which Rubner devoted his remarkable talents, and the practical results of much of his work may not be as apparent as those of modern pioneers. But Rubner's name will remain as that of a pathfinder in the science of nutrition.

PHYSIOLOGICAL EFFECTS OF ALUMINIUM

For 30 years and more there have been smouldering doubts about the use of aluminium cooking-pots. Lately, in some quarters, these doubts have quickened into a flame, and its heat has stimulated some of the appropriate authorities to review the evidence.[1] The latest reviewer is Dr. J. H. Burn, director of the pharmacological laboratories of the Pharmaceutical Society of Great Britain, who on June 1st addressed the Society of Public Analysts on the Physiological Effects of Aluminium. The first extensive investigation of these effects, he said, was made in 1886 by Siem, working under Prof. H. H. Meyer. Siem found that doses corresponding to grs. 30 to 40 of alumina for a man had no effect when administered by mouth to cats daily for four weeks. When the aluminium salt was injected under the skin, the fatal dose varied from 0·25 to 0·30 g. of alumina per kg. These results, indicating that aluminium has some toxicity when injected but is harmless by mouth, have in substance been confirmed by many subsequent workers. Siebert and Wells examined the pathological changes produced by injecting alum and aluminium chloride; they found that anæmia was manifested after nine or ten daily injections, a fall in the hæmoglobin percentage and in the red cell count being recorded. In the spleen, pigmentation, thrombosis, and fibrosis were observed. The experiments of McCollum and his colleagues, and those of Myers and Mull, show conclusively that the addition of aluminium salts to the diet of young rats has no ill-effect on growth, health, and reproduction, even when four successive generations are observed. Those of Myers and Morrison, and of Underhill and Peterman, show that when aluminium compounds are given by mouth to dogs, only insignificant changes in the amounts of aluminium in different tissues are found, and it follows that aluminium salts are not absorbed from the alimentary tract, except in traces. As a result of a scare in the United States, that the use of aluminium baking-powders was dangerous to health, the Department of Agriculture instituted an inquiry. The report, published in 1914, describes experiments on 26 university students carried out in three different universities, who were given amounts of alum varying from 0·2 to 10·0 g. daily for about six months. It was unanimously reported from the results of these experiments that the amounts of alum likely to be consumed as a result of the presence of alum in baking-powder—estimated as a little over gr. 1 of aluminium per person per day—are much too small to have any ill-effect. The amounts of aluminium to be found in food cooked in aluminium vessels are estimated from analyses carried out by Massatch to be about gr. 1/10 per person daily. It is seen that the dangers arising from aluminium utensils have been thoroughly investigated by many workers, on many species of animals; they have also been investigated with equal thoroughness on man. These dangers, said Dr. Burn, are non-existent; and clinical reports that symptoms of abdominal pain are relieved by discontinuing the use of aluminium must be ascribed to psychological effects, which are very common in medical practice.

OCULAR MOVEMENTS

IN his Bowman lecture, delivered at the recent annual congress of the Ophthalmological Society of the United Kingdom, held at Edinburgh, Prof. J. van der Hoeve began by touching on Bowman's friendship with the leading Dutch ophthalmologists of his time. The close association of the two countries at that time in ophthalmological matters had, he said, happily persisted until now. He then gave a masterly description of the extrinsic musculature of the eyeball, of the movements executed by it and of the mechanism of these movements. He compared the movements of the human eyes with those of the rabbit, in which animal the absence of a macula and the slightness of the overlap of the visual fields causes considerable modification of the ocular movements. He showed how the action of each ocular muscle alters according to the primary position of the globe; in fact, the more the mechanism of ocular movements is studied the more complex the question is found to be, for even the simplest movement is executed by the agency of a perfectly balanced synkinesis of all 12 muscles. By means of explanatory diagrams, sketches, and photographs, Prof. van der Hoeve reviewed the experiments which had been carried out in the past on animals and men in the investigation of ocular movements. The simpler animal experiments consisted of photographing the eyes of an animal which was subjected to various movements in space on a board capable of rotation in any plane; compensatory movements of the eyes during these passive movements were elicited. Similar experiments were performed on the human subject, bound to a revolving stretcher capable of similar complex movement; the same apparatus was used in the investigation of nystagmus. More complex, though more portable, apparatus was used by the investigators, mainly Dutch and German, of the existence and position of the centre of rotation of the eyeball. As a result of his own studies, and from a consideration of the work of others, Prof. van der Hoeve has been forced to the conclusion that there is no such thing as a fixed centre of rotation for the eye, but that rotation occurs around a point most suitable and most economical for the particular movement which is being carried out. The formula which has hitherto been accepted—that rotation of the globe occurs around a fixed point, with the ocular muscles acting in a line from the centre of their origin to the centre of their insertion—must be abandoned, and the alternative accepted, that the eye goes about any particular movement in the easiest, simplest, and quickest way, irrespective of the movements which preceded it or are to follow it. The lecturer hinted at the likelihood even of separate fibres of the same ocular muscle having different actions under different conditions. At the conclusion of his lecture Prof. van der Hoeve referred to the question of periscopic spectacle lenses designed and fitted with respect to a fixed centre of rotation of the globe. The idea underlying their prescription and use was, he said, a mistaken one. So far from their being peculiarly adapted to the globe in its movements, it was likely that the globe adapted itself to the glass. Hence the desired optical result was achieved in the end.

OUR HOSPITALS

THE second issue of the Hospitals Year Book[1] is far more convenient to handle than its predecessor, since the directory, which occupied more than half its pages, has been omitted. This omission allows the insertion of interesting surveys of various aspects of hospital work. The volume, which measures roughly 11 by 9 inches, is divided into two parts. Part I., which takes up 169 pages, contains a brief financial review by Sir Charles Harris, honorary financial consultant to the Central Bureau of Hospital Information; a general survey of the work and finance of voluntary hospitals in Great Britain and Ireland for the year 1930; and notes on the Road Traffic Act, 1930, on new hospital buildings, and on the relationship between the voluntary hospitals and the local authorities under the Local Government Act, 1929. The report by the Joint Committee of the Association and the British Medical Association on the payment of visiting medical staffs of voluntary hospitals is set out in full, and the rest of this part of the book is taken up with tables. These provide information on the volume of work done in voluntary hospitals, and on the income and expenditure on maintenance account, with an analysis of the sources of income and the principal items of expenditure. The average cost of in-patients and out-patients in general and special hospitals is also tabulated. Less detailed accounts are supplied of the work and staffing of municipal and public assistance hospitals, mental hospitals, and sanatoriums. Part II. of the Year Book contains, among other material, an article on road accidents by Sir Alexander Butterworth, an appreciative note on THE LANCET Commission on Nursing, of which the recommendations are set out in full, an account of the work and conditions of training of a hospital almoner, a tabulated list of new buildings or extensions completed by voluntary hospitals during the last two years, and a list of memoranda on matters of administrative interest to hospitals, prepared by the Central Bureau of Hospital Information. Most of those have already been published, but Nos. 38 to 50 are here set out. They deal with contributory schemes, the domestic and nursing staffs of hospitals associated with medical schools, the conditions under which medical staffs give their services in cottage hospitals where the hospital is in receipt of income from contributory schemes, the duties of a senior resident medical officer, and so forth.

---

[1] An Annual Record of the *Hospitals of Great Britain* and Ireland, issued under the auspices of the British Hospitals Association and the Joint Council of the Order of St. John and the British Red Cross Society. London: Central Bureau of Hospital Information. 1932. Pp. 268. *7s. 6d.*

In a foreword to the Year Book, Sir Arthur Stanley points out that in 1930 the income of the voluntary hospitals for the year exceeded their expenditure by nearly £750,000, though, since this surplus was divided unevenly, some hospitals remained in dire need at the end of that year. He calls attention also to the growth of accommodation, amounting to 1500 beds in the year. That the year under review is 1930 and not 1931 is regrettable, for information so out of date, however cheering, can have little bearing on the position to be faced now that we are approaching the second half of 1932. Sir Charles Harris reproaches the hospitals themselves for this lag period, since less than half of those outside the scope of King Edward's Hospital Fund for London, which insists on early returns, sent in the annual reports from which this volume is largely compiled in the first half of 1931, and 10 per cent., including some large hospitals, delayed till November or even December of that year. He complains also of the imperfect standardisation of the records and accounts, which though rectified "for all practical purposes" in this volume, involved correspondence and further delay in the date of its issue. A plaint even more serious, because it is addressed to voluntary hospitals as a whole, and not only to defaulters, is implied in the paragraph which concludes the section of the Year Book dealing with the definition of their relations with local authorities. The intention of the Local Government Act, 1929, was obviously, as is here stated, to lay quietly and without hurry the foundations of a bridge between two organically different bodies, each now charged with more or less similar duties. But, the argument continues, no public authority having determined on a policy embodying certain broad principles can be expected to modify it in many different ways to suit the views and wishes of each individual hospital. It is essential, therefore, that the voluntary hospitals should endeavour not only to think collectively but also to strengthen the machinery for expressing their considered views. It is true that the essence of the voluntary system lies in the independence of the units forming it, and that any measure of active central control that deprived them of that independence would probably mean their end; but central control and joint action are distinct things, and just as the former would end the voluntary hospitals, the want of the latter, in the view of their own central organisation, will inevitably bring about the same result. We ourselves are not so certain of this; the voluntary hospitals have survived for long on a basis of individualism and rivalry rather than coöperation. But a plea expressed by those who have evidently sought in vain to induce them to speak with one voice should not be lightly dismissed.

It is reinforced by the coöperation achieved between those hospitals which come within the scope of King Edward's Hospital Fund for London, the annual meeting of which was held on June 7th. It is a notable achievement that this Fund has been able not only to increase its distribution, but to add substantially to reserve. The Prince of Wales, who presided at the meeting, was able to say that in 1931 the voluntary hospitals in London had, as a whole, more than balanced their budgets, the total of the surpluses (in 82 hospitals) exceeding the total of the deficits (in 57 hospitals) by £65,000. The Prince called for an intensive effort to reinforce the weak spots, while still keeping up supplies to the rest, and this message has a wide application.

INTERMITTENT GROWTH OF CHILDREN

AN investigation by the department of biology and public health of the Massachusetts Institute of Technology[1] has had some suggestive results which may have a practical application. Children in certain elementary schools were weighed regularly every month, always at the same time of day, and the extent to which growth was intermittent was noted, the children being classified on the basis of whether they failed to gain for one, two, or more months. Comparison was then made between a group who had failed to gain weight over a period of three months and a control group who had never failed to gain in a two-month period during a whole year, in respect of their health habits as regards diet, sleep, and exercise, and the presence or absence of defects or diseases. The results show that whilst intermittency in increase of weight does not differentiate absolutely between children who do and who do not require attention, yet it has significance which cannot be overlooked. Serious physical defects were nearly three times as numerous, and affected twice as many children, in the former group, while nearly three times as many also had two or more important unhygienic habits, such as insufficient protein and vitamins in the diet, inadequate sleep, or deficiency of liquid and roughage. The results point to the value of regular weighing of all children. This is, of course, a routine practice in child welfare clinics, nursery schools, and open-air schools. School medical inspection provides for the taking of heights and weights, but in many areas this is not carried out and in any case the four-yearly intervals between the routine inspections render such measurements valueless for the individual child. From the observations in Massachusetts it seems desirable to weigh all children of school age, either at monthly or at least three-monthly intervals, and to refer all those failing to gain over a period of three months or more for examination as "specials" in the scheme of medical inspection. Failure to gain, or even loss of weight, may not always be important, and must always be judged in relation to other factors; but these would be matters to be determined by the examining doctor.

Sir Henry Wellcome has been elected a Fellow of the Royal Society. Among the new foreign members are Mr. Graham Lusk, professor of physiology in Cornell University Medical College, New York, and Prof. Theobald Smith, director emeritus of the department of animal pathology of the Rockefeller Institute of Medical Research.

Sir Arthur Keith, F.R.S., will deliver the Stephen Paget lecture at the annual general meeting of the Research Defence Society to be held at the London School of Hygiene and Tropical Medicine at 3 P.M. on June 15th. His subject is Some Aspects of the Modern Conflict between Reason and Sentiment.

WHAT IS WRONG WITH THE MEDICAL CURRICULUM?

(A Series of Opinions Contributed by Request).

I.

BY MAJOR GREENWOOD, D.SC., F.R.C.P., F.R.S.,
PROFESSOR OF EPIDEMIOLOGY AND VITAL STATISTICS IN THE UNIVERSITY OF LONDON.

THE object of this symposium on medical education is, I believe, to focus the criticisms of persons whose experiences have been in different fields of medical work. The possession of a registrable diploma in medicine does not qualify its holder to be a judge of *all* the needs of *all* medical men. As a boy I lived in the atmosphere of an east end general practice; as a very young man I spent four happy years as the assistant of a great physiologist. These experiences, however profoundly they may have influenced my personality, give me no title to pose as an expert critic of either clinical or laboratory teaching. Such claim as I have to express *any* opinion upon educational questions is based upon a rather peculiar experience. It has been for a good many years part of my duty to read and criticise reports and papers dealing with an immense variety of subjects within the field of medical science. The only common factor has been that the writers had treated or, it was thought, ought to have treated some of the subject matter from a quantitative or statistical point of view. Not infrequently the purely numerical aspect has been of minor importance, my colleagues on the Statistical Committee of the Medical Research Council and I have had to consider primarily the logical value of the arguments presented. The result is that, leaving entirely out of account specific issues of private or public controversy in respect of which one's judgment is clouded by personal predilections and vanity, I have had rather exceptional opportunities of gauging the qualities of medical literature. I wish first to try to compare the general characteristics of what my colleagues and I read now with what used to come to us as individual critics 20 years ago.

RELIANCE ON TECHNIQUE.

The most striking difference is certainly an increasing reliance on technique. Even as recently as 20 years ago medical writers would still challenge peremptorily the demand that their data should be treated statistically at all. For fairly obvious reasons I do not think their objections were logical, but the point is that they did state objections of principle. That attitude has passed away. The writer, who 20 years ago would have said that statistical method was mere "mathematical" juggling having no relation to "practical" matters, now seeks for some technical "formula" by the application of which he can produce "significant" results. I am not so poor a psychologist as to neglect the consideration that a committee of experts, or even an individual "professor" of 51, will be approached more tactfully than an unknown young man of 31, but I do not think that is a complete explanation; the change is more fundamental. To put it epigrammatically, and therefore, of course, to overstate it, the change has been from thinking badly to not thinking at all, from thinking that statisticians were triflers to believing that statisticians are patentees of more or less powerful magic. The professional credit of expert statisticians has increased but there has been no dissemination among medical writers of the *principles* of statistical reasoning. Medical papers now frequently contain statistical analyses, and sometimes these analyses are correct, but the writers violate quite as often as before, the fundamental principles of statistical or of general logical reasoning.

This is not peculiar to the special case of statistics; I have sufficient recollection of the principles of physiology to perceive that this branch of science has been treated in the same way. Much more use is made of the technical vocabularies of particular branches of experimental physiology, in particular of those concerned with the nervous system, the endocrine system and general metabolism, but the method of use often moves the real adepts to laughter or tears. One finds loose verbal analogies passing as deductions and mere jargon masquerading as precise, scientific exposition.

DECREASING LITERACY.

A correlative change is decreasing literacy. Most examiners have, I suppose, noticed this. On the whole the standard of expression in the examination papers of post-graduate candidates now is, I think, not higher than that of undergraduates in the medical schools 25 years ago, and editors make the same complaint. I do not wish to exaggerate the importance of this. Many people reason well who write ill; some—not very many—write beautifully and reason badly. Perhaps the schoolmasters of one or more generations ago overstated the claims of a literary education. The case made by the teachers of our teachers against a "classical" education and in favour of the natural sciences as instruments of culture was that the average boy or girl never acquired a sufficient mastery of the mere technique of grammar and vocabulary for Latin and Greek literature to become for them an instrument of mental training. On the other hand, the "facts" of the natural sciences were intrinsically interesting to young people who might be spurred on by that interest to take pains to understand the difficult processes of thought which had led to the discovery of such exciting things. Even 50 years ago there were men of science who had doubts. I think the great physicist Tait was one of these; he argued that science was very hard, that its study was best begun at a comparatively mature age, *after* a schooling in "dull" logical, mathematical reasoning, and that difficulties did not vanish because one ignored them. Tait would have been horrified by the suggestion that an average boy or girl of from 16 to 17, whose general education was defined by the standard of a school-leaving certificate, was fit to be subjected to an exclusively scientific-technological course of instruction. Yet that is the fate of the rank and file of medical students. At the age of 17 their training begins to acquire a flavour of technicality, and within a few years it becomes wholly technical. Very few teachers of the "preliminary" and no teachers of the "intermediate" subjects are bold enough to maintain that they neither know nor care whether the "facts" and technical manipulations which are incidental to their teaching are of practical use to medical men, and that they mean to use chemistry, physics, biology, human anatomy, or physiology primarily as instruments for training their pupils to observe accurately and think logically.

I have indeed heard "intermediate" teachers, none of whom had ever treated a patient in their post-graduate lives, waxing eloquent over the unpractical attitude of the "preliminary" teachers and urging that the students ought to be taught *useful* physics, how to wire a switchboard and handle X ray apparatus, instead of unpractical general principles. These apostles of the practical forget quite recent history. A majority of London-trained medical men over 60 were taught anatomy and physiology by surgeons and physicians. The present generation of whole-time specialist teachers of "intermediate" sciences owe their existence to a belief that the educational not the mere technical value of the sciences of physiology and anatomy was too great for it to be right to make the teaching of these subjects a subsidiary occupation. In these economically strenuous times there are plenty of clinicians who know from practical experience, better even than physiological Fellows of the Royal Society, not how much physiological technique *ought* to be, but how much *is* "practically" useful to a "doctor," and are quite willing to impart that modicum without aspiring to become whole-time university professors. In the end the men of science may find themselves relegated to research institutions and their pupils reduced to a small number of really educated people. That is, of course, quite an attractive prospect from the point of view of any scientific man who cares for his work; anybody who cares for his subject must indeed be altruistic to refrain from supporting a policy which may have such a consummation. But a majority of "intermediate" and "preliminary" teachers are, I suspect, altruistic enough really to care about the education of young people, and to believe that trying to mould the unpromising clay of a semi-literate child of 17 into something not preposterously unlike a young man or woman with a disciplined mind, is almost as praiseworthy as writing papers in the *Philosophical Transactions* or prescribing for Cabinet Ministers. Most of them recognise that the innate variation of human aptitudes is so great that while A can be trained to think by the use of the concepts and methods of, say, physics, but can make nothing of biology, to B physics are mere sound and fury, something to be memorised, but biology is fascinatingly instructive.

REMEDY—A WIDER LATITUDE OF CHOICE.

Hence it might be suggested that instead of forcing all students through the same educational mill, a wider latitude of choice should be permitted, that those who can learn to think in the biological laboratory should be encouraged to spend more time there and less in the physical laboratory, and that the key of the wards should not be a stereotyped common examination but an individualised special examination. We might even go further and support the paradox that proof of having mastered *any* branch of human knowledge, from Greek philology to pure mathematics—so far as a youth can be said to have mastered anything—should admit a student to the clinical stage. My experience of training post-graduates who have come into epidemiological and medical-statistical work from a wide range of occupations is that *any* kind of serious intellectual discipline is better than the general smattering of technical medical knowledge which is all some young medical graduates seem to have acquired. That is confessedly a narrow and highly specialised experience, but I suspect that an educational experiment well worth trying would be to dispense a certain number of good honours graduates in non-medical subjects, humanistic or scientific, from the pre-clinical stages, and to try them out ten years later against our ordinary mass products. Of course they would have had to learn, by their own efforts and in their own time, much which the others knew. But, having learned how to learn, they would, I believe, succeed.

I have the impression—it may, of course, be a mere illusion—that we medical folk are a little too prone to claim for our curriculum virtues which our opposite numbers in the legal profession do not claim on behalf of *their* undergraduate training. Three sons of a middle-class family choose, or have chosen for them, the professions of barrister, solicitor, and "doctor." In real life, as we all know, after one has been called, another admitted, and a third qualified, each must spend laborious and unremunerative years in really learning how to practise. The Bar Council and the Law Society do not, I think, pretend that the courses of training they prescribe render young people of 22 to 25 competent to perform all or even most of the tasks which an abstract "public" might expect an ideal "lawyer" to be able to carry through. I think we do, implicitly if not explicitly, make the claim that young "doctors" are in some mysterious way better equipped to grapple with quite as difficult tasks as come the way of "lawyers," than fledgling barristers or solicitors are fitted for their duties. Why? Surely not because the intellectually most brilliant member of the family is always chosen to become a "doctor." Equally surely not because the medical profession is reserved for the son or daughter who has had the best general education. Perhaps it is a relic of the priestly tradition—some of us *are* rather fond of talking about the laity with a certain superiority. The one claim as against the legal profession which can be made is that our under-graduates are put through a much fiercer technical drill. But, if that is not based upon a sound general education, we must be turning out not commissioned officers but corporals and drill sergeants, or, to change the metaphor, not motor engineers but garage hands. I do not think Mr. Bernard Shaw is the only *layman* to notice how poor a show even highly successful "doctors" often make when they are engaged in controversy or are speaking pontifically on border-line questions, such as the rights and wrongs of vaccination, psycho-analysis, or the cause of cancer. What the "doctor" says is very often not evidence; the "doctor" has never been taught what is and what is not evidence. Perhaps a little more familiarity with general principles and a *little less familiarity* with the technique of new "therapies" is a prescription which might be tried.

DR. BARNARDO'S HOMES: ANNUAL MEETING.—At the annual general business meeting of Dr. Barnardo's Homes: National Incorporated Association held on May 18th it was stated that 111,501 destitute boys and girls had entered the homes up to the end of last year, and that 17,019 children and young people were dealt with during 1931. In that year 1643 boys and girls and babies were admitted to the benefits of the homes—1340 permanently and 303 temporarily—and 8247 were in residence. These included 1319 children under 5; 447 sick, crippled, or afflicted children; 1124 boys and girls under industrial and technical instruction; and about 400 in training for the Navy and mercantile marine. The homes have no waiting-list and no voting system. The head offices are at 18 to 26, Stepney-causeway, London, E.1.

GENERAL MEDICAL COUNCIL

SUMMER SESSION, JUNE 2ND–5TH, 1932.

Committee Work

THE NEW PHARMACOPŒIA.

Sir Donald Macalister, chairman of the Pharmacopœia Committee, laid before the Council the completed text of the British Pharmacopœia, 1932. It was, he said, rather larger than the 1914 edition, chiefly because of the work of the League of Nations in framing international methods for controlling processes and standardising drugs. The cost of production had inevitably been greater, and the Committee recommended that the price should be 21s., with large-paper copies 10s. extra. Copies would be exposed for inspection in the offices of the Council in London, Edinburgh, and Dublin for three months before publication. An edition of 30,000 copies was to be printed of which 20,000 would be bound. The report contained a warm expression by the Committee of its thanks to Dr. A. P. Beddard, the chairman, and the members of the Pharmacopœia Commission, and to all their helpers. The Commission will remain in office until Sept. 30th, 1933, to deal with matters arising out of the new text.

TEACHING OF PREVENTIVE MEDICINE.

The recommendations of the Society of Medical Officers of Health for the teaching of preventive medicine have been under the consideration of the licensing bodies. The opinions of these bodies, with one exception, have now been received, and were submitted to the Council by the joint Education and Examination Committee specially formed to deal with the recommendations.

With five exceptions the licensing bodies appear to demand a separate examination in public health and preventive medicine, but they are disinclined to make the regulations governing admission to this examination more comprehensive or standardised. There is, however, general approval of the recommendation that teachers in the various subjects should coöperate in the teaching of preventive medicine. A number of replies state that questions upon the preventive aspects of medicine are from time to time included in the final examination. In a number of centres a local medical officer of health is taking part in the training of medical students, and in almost all cases visits to institutions of public health interest are arranged. On the number of those lectures in the course in hygiene and public health which deal more particularly with the prevention of disease in the community, there is a difference of opinion. The University of London and the English Conjoint Board do not approve of any extension of the teaching by specialists in preventive medicine, taking the view that the interests of medical education are best served by the teachers in each of the clinical subjects coöperating in the training of students in the methods of prevention of disease.

EDUCATION OF STUDENTS BEFORE REGISTRATION.

Prof. James Rice's report on the pre-registration examinations was submitted by the President, as chairman of the Examination Committee. The most significant point in Prof. Rice's classification of the various methods of the licensing bodies is the question of whether or not instruction and examination in chemistry and physics are insisted upon after the medical curriculum has been commenced. It was never, the Committee pointed out, the intention of the Council to recommend that the pre-registration examination should be the sole test in chemistry and physics. In the resolutions of 1923, it seems to be understood that there shall be further instruction in chemistry and physics "in their application to medicine" after passing the pre-registration examination, but it is by no means made clear. Much confusion has arisen with regard to the interpretation of this double reference to the teaching of chemistry and physics, and the reports make it evident that the exact meaning of this resolution must be defined. It is around the precise interpretation of these paragraphs that most of the difficulties concerning the pre-registration examination appear to centre.

The Committee considers that while the introduction of a pre-registration examination in chemistry and physics, with further instruction in them after registration, does not materially reduce the time devoted to pre-clinical studies, it can definitely improve medical education. If a student embarks upon his medical course with a grounding in chemistry and physics, it is possible for him to attend more advanced courses, which can be adapted to his special needs, during the first terms after registration. However, in order to gain the fullest benefit from the pre-registration examination, it is of the utmost importance that the post-registration courses in chemistry and physics should be adjusted very carefully to the needs of a medical student, and coördinated as far as possible with the further study of these subjects at later times in the curriculum. The post-registration courses would thus serve as a natural stepping-stone to the development and application of chemistry and physics in physiology, pharmacology, pathology, and clinical work, ensuring a fuller and more relative knowledge of the subjects and a greater cohesion between teaching and application.

OBJECTIONS TO THE EXAMINATIONS.—The Committee, in its report, reviewed the more serious objections to the pre-registration examination. The first of these is that, although a large proportion of secondary schools can teach chemistry and physics well enough for the examination, others cannot; consequently the teachers of chemistry and physics in the medical schools are confronted by students at two levels; some have passed a pre-registration examination and others know nothing about the subjects. The difficulties created by this situation have been met in various ways, not all of them satisfactory to Prof. Rice. Since, however, an increasing number of secondary schools are making arrangements to give adequate instruction in elementary chemistry and physics, this objection will probably lose much of its significance in most centres. The resolutions of the Council have not yet had their full effect upon the secondary schools. Many schools have made special provision for the science training of future medical students, expecting that their responsibility will continue.

Another objection is that to encourage the study of chemistry and physics in the later years at school may lead to too early specialisation and to the neglect of general education. The Committee admits the importance of the point, but emphasises Prof. Rice's opinion that the pre-registration standard should not be as high as that of the higher school certificate, and should be obtainable in a year. It seems, the report remarks, doubtful, considering the recent speeding-up of the school curriculum, whether the considerable advantage gained by a student who knows the main principles of chemistry and physics before entering on a medical course does not outweigh this danger. The same consideration also answers the third objection—that the pre-registration examination merely adds an unnecessary hurdle.

The Committee therefore gave as its opinion :—

1. That a knowledge of elementary chemistry and physics before entrance upon the medical curriculum is desirable.

2. That such knowledge of elementary chemistry and physics must be supplemented by further instruction and

examinations in these subjects in their relation to medicine during the first year.

3. The courses in chemistry and physics included in the curriculum should be adapted to the special needs of the medical student and coordinated with the teaching in the later stages of the curriculum.

Prof. J. B. S. STOPFORD, in introducing this report, said that the Committee was still at the inquiry stage; educational matters were involved and further information was needed from the licensing bodies.

Mr. K. W. MONSARRAT asked the Council to consider the advisability of including biology in the early training.

Sir H. B. BRACKENBURY was also of opinion that biology ought to enter into the picture of these preliminary studies. The secondary schools made considerable provision for the teaching of chemistry and physics, but not much for the teaching of biology; in the last five years however such provision as existed had been greatly extended and improved. The time, he thought, had come when the Council should say something to encourage the schools that made this provision.

OPHTHALMIA NEONATORUM.

Prof. J. B. LEATHES, chairman of the Education Committee, presented its report. The Committee had, he said, received from the British Medical Association the following resolution of its Representative Body:—

> "That the Council of the B.M.A. should point out to the General Medical Council that it is desirable that medical students should have opportunities of studying the care and treatment of ophthalmia neonatorum, the best time for such instruction being during attendance on the course of fevers."

and the Committee had resolved as follows:—

> "That the British Medical Association be informed that it was intended that the care and treatment of ophthalmia neonatorum should be included under 'Diseases of the Eye' in the resolutions of the Council in regard to professional education, and it was not considered expedient to refer to specific diseases by name or to define how and where opportunities for studying them should be obtained."

Mr. BISHOP HARMAN considered the answer quite a good one, but the difficulty was that it did not meet the new conditions of treatment. Nowadays infants and their mothers were removed at once on notification to special hospitals; and the student in the general hospital did not get a chance of seeing cases. It was quite impossible to impress upon students the serious consequences of the disease unless they could be shown cases.

Mr. H. L. EASON corroborated Mr. Bishop Harman's remarks from his experience at Guy's Hospital. The disease had been extinct for several years in the school's maternity district, and cases which arose outside it were sent direct to an institution.

Dr. J. W. BONE thought that ophthalmia neonatorum should be removed from the group of "diseases of the eye" and considered as a "fever."

Mr. HARMAN said it had not been intended that the teaching of ophthalmia neonatorum should be withdrawn from its proper place in the curriculum, but the special hospitals where it was treated were regarded as fever hospitals. It had been proved to be a fever in order that the Metropolitan Asylums Board should make provision for it in a fever hospital. Hence the present problem.

The PRESIDENT said it was a matter for the schools. It should be easy for a teacher to make arrangements for his students to see these cases.

MEDICINE AND THE LAW

Prompt Notification of Accident

THE Workmen's Compensation Act stipulates that an employer shall receive notice of a workman's accident "as soon as practicable after the happening thereof," unless it is found that the employer was not prejudiced by the want of notice, or that the want of notice was occasioned by "mistake, absence from the United Kingdom, or other reasonable cause." Naturally the workman's excuse for delay in notifying will usually be that he thought at first that his injury was trivial. This answer has been held insufficient in itself, though of course the decided cases turn each upon its own set of facts.

Here is a case recently decided by the House of Lords. In November, 1929, a 17-year-old workman injured his shoulder while employed in shifting pit-tubs for a colliery company. He mentioned his injury to a fellow-workman, rested several minutes, and finished his shift with assistance, then went home, told his mother, and lay down on a sofa. According to his mother he became muddled in his mind that evening, and was unable to get off the sofa, and so continued till he went to hospital in January. According to the doctor, who saw him on the day after his injury, the boy was rational and master of himself for three or four days, and seemed likely to be all right in a week. After four days the doctor diagnosed septic arthritis; the patient underwent nine operations in hospital owing to osteomyelitis, and came out a complete wreck in the following May. No notice of the accident was given before March, the boy explaining that he thought at first his injury was trivial. The county court judge found that (1) osteomyelitis developed after the injury which was therefore an accident; (2) the employers were not prejudiced by non-notification because no more could have been done for the patient than was actually done; and (3) the boy reasonably thought his accident was trivial at first, and afterwards was not in a condition to give notice; for these reasons the judge held that there was reasonable cause for the delay in giving notice. The Court of Appeal overruled this decision on the grounds that (1) notice was not given as soon as practicable, and there was no reasonable cause for the delay because the county court judge had accepted the doctor's evidence which showed that the workman was in a condition to give notice during the first few days; (2) the boy's belief that his injury was trivial was no excuse; (3) the employers were prejudiced in their defence by the want of notice because, the question being whether or not the osteomyelitis was latent in the patient at the time of the accident, it was vital for the employers to have had the chance to examine the workman as soon as possible after the injury. In confirming this decision the House of Lords has ruled that the employers were prejudiced and that there was no reasonable cause for non-notification. If the case seems a hard one, it was only reasonable for Parliament to enact, and only right for the law courts to enforce, the general principle that there should be facilities for prompt medical examination of the workman at the earliest possible moment.

Coroner on Osteopath's Treatment

At a recent inquest at Southend the deceased was reported to have had a dislike of doctors. He was attended by an osteopath. A medical practitioner gave evidence that he had examined the patient and had advised calling in a surgeon. This led to an argument on the merits and demerits of surgeons, and the advice was not followed. Sir Bernard Spilsbury, who conducted a post-mortem examination, found death to be due to a large abscess near the kidney; had the patient taken the doctor's advice and undergone an operation, there was every chance, said Sir Bernard, of a complete cure. The osteopath gave evidence that he had provisionally diagnosed an accumulation of urine in the kidney and the pelvis. The widow apparently said that the osteopath told her as late as the morning of his death that her husband was all right and that there was nothing wrong. The coroner observed that there was no evidence which would justify the finding of manslaughter which normally follows if anyone undertakes the responsibility of caring for life and is guilty of gross negligence whereby life is lost. In the coroner's view, however, the osteopath's diagnosis was wrong; the osteopath should have seen that the patient was gravely and seriously ill and required the attention of a qualified medical practitioner. The osteopath should have advised the calling in of such a practitioner. There was nothing grossly wrong in the treatment administered by the osteopath: it was of no practical good or effect.

IRELAND

(FROM OUR OWN CORRESPONDENT.)

THE IRISH HOSPITALS SWEEPSTAKES.

THE sweepstake on the recent Derby has attracted more money than any of the previous ones. The total receipts amounted to £4,128,484, of which the share for the hospitals should be 25 per cent. or £1,032,121. Only half of this sum, however, will reach the voluntary hospitals, as the Minister for Finance is enacting a levy of 25 per cent., and the rate-supported institutions draw 33 per cent. of the remainder. The voluntary hospitals will, therefore, in fact, benefit less than they did from the Grand National sweepstake, the sum due to them from that event being £560,885. Last week in the Dail, Dr. Ward (parliamentary secretary to the Minister for Local Government and Public Health), in answer to a question, stated that the amounts available for the poor-law hospitals from the sweepstakes on the November Handicap of 1931 and the Grand National of 1932 were £236,721 and £270,158 respectively. He said that the money would be distributed according to local needs with regard to the area and the population to be served, the urgency of the work proposed, and local financial and economic circumstances. He added that if there was any delay in dealing with the distribution or release of the money it would be due to the failure of the local authorities to submit the necessary plans and specifications.

It is understood that the report of the committee of reference on the distribution of the funds available from the November Handicap sweepstake has been handed to the Minister for Justice. It is hoped that the committee may have something to say on the general question of a hospital policy for Ireland, and in particular for Dublin.

ASSOCIATION OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

For some time past plans have been on foot to establish an Association of the Royal College of Surgeons in Ireland, and the Association was formally constituted on June 3rd, when a meeting of Fellows and Licentiates was held and rules adopted. Sir William Taylor was elected President, and Dr. J. P. Brennan and Mr. James Smith honorary secretaries. Some 500 past students are already members. On the evening of June 4th the Association celebrated its birth by the members dining together in the College. Sir William Taylor was in the chair, and there was a large number of members and guests present. The President of the College, Mr. R. A. Stoney, in responding to the toast of the College, said that it was in a most flourishing condition. They had over 60 new students entering the schools within the past year.

JUBILEE OF THE ROYAL ACADEMY OF MEDICINE.

The Royal Academy of Medicine in Ireland celebrated its jubilee on May 27th by a conversazione. Prof. T. G. Moorhead, the President, gave a brief account of the history and work of the Academy. It was founded in 1882 by the amalgamation of five older societies—the Medical Society, the Surgical Society, the Pathological Society, and the Obstetrical Society. These societies had themselves a venerable history, the Surgical Society being then in its fiftieth year while the Medical Society was a few years older. At least five of the original members of the Academy survive,—Sir John Moore, Sir William Smyly, Dr. Richard A. Hayes, Dr. J. C. O'Carroll, and Dr. H. W. Oulton. In its 50 years of life the Academy had kept in the front of medical progress, and had enhanced the reputation of the Dublin school. Dr. Moorhead asked the Academy to accept, as a gift from him, a badge to be worn by future presidents. The badge is a beautiful piece of enamel work.

The President's brief address was followed by a lecture on Sir William Petty, delivered by Dr. T. P. C. Kirkpatrick. Dr. Kirkpatrick gave a very interesting account of that remarkable man, at once man of science, administrator, and geographer, holding at one and the same time the professorship of anatomy at Oxford, the professorship of music at Gresham College, London, and the physician-generalship of the Army in Ireland.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. D. A. Newbery to be Surg. Lt.-Comdr.
L. G. Yendoll to be Surg. Lt.
Surg. Lt.-Comdr. J. G. Holmes is appointed to *Coventry*.

ROYAL ARMY MEDICAL CORPS.

Col. J. C. Kennedy, late R.A.M.C., is placed on half pay.
Lt.-Col. P. J. Hanafin, from R.A.M.C., to be Col.
Maj. C. H. O'Rorke retires on retd. pay.

TERRITORIAL ARMY.

Lt.-Col. C. Corfield, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

Lt. N. H. Watson to be Capt.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. Ross retires.
Capt. J. N. Madan relinquishes his temp. commn.

ARMY EXAMINATIONS.

The results of the examination (in written subjects) of officers, with a view to promotion in the Royal Army Medical Corps, which was held in March last, are as follows: Majors J. C. Denvir, G. D. Grippen, G. Moulson, A. K. Robb, P. A. Stewart, G. K. Fulton, and J. D. A. Champney, and Capts. W. L. S. Cox and A. E. Campbell.

COLONIAL MEDICAL SERVICE.

Dr. F. H. N. Cruchley has been appointed Medical Officer, Jamaica; Dr. R. S. Begbie, Assistant Bacteriologist, Hong-Kong; Dr. J. P. Fehily, Health Officer of Port and Inspector of Emigrants, Hong-Kong; and Dr. J. H. Pottinger, Assistant Government Medical Officer of Health British, Guiana.

examinations in these subjects in their relation to medicine during the first year.

3. The courses in chemistry and physics included in the curriculum should be adapted to the special needs of the *medical student and coördinated with the teaching in the* later stages of the curriculum.

Prof. J. B. S. **Stopford**, in introducing this report, said that the Committee was still at the inquiry stage; educational matters were involved and further *information* was needed from the licensing bodies.

Mr. K. W. **Monsarrat** asked the Council to consider the advisability of including biology in the early training.

Sir H. B. **Brackenbury** was also of opinion that biology ought to enter into the picture of these preliminary studies. The secondary schools made considerable provision for the teaching of chemistry and physics, but not much for the teaching of biology; in the last five years however such provision as existed had been greatly extended and improved. The time, he thought, had come when the Council should say something to encourage the schools that made this provision.

OPHTHALMIA NEONATORUM.

Prof. J. B. **Leathes**, chairman of the Education Committee, presented its report. The Committee had, he said, received from the British Medical Association the following resolution of its Representative Body:—

> "That the Council of the B.M.A. should point out to the General Medical Council that it is desirable that medical students should have opportunities of studying the care and treatment of ophthalmia neonatorum, the best time for such instruction being during attendance on the course of fevers."

and the Committee had resolved as follows:—

> "That the British Medical Association be informed that it was intended that the care and treatment of ophthalmia neonatorum should be included under 'Diseases of the Eye' *in the resolutions of the Council in regard to professional* education, and it was not considered expedient to refer to specific diseases by name or to define how and where opportunities for studying them should be obtained."

Mr. **Bishop Harman** considered the answer quite a good one, but the difficulty was that it did not meet the new conditions of treatment. Nowadays infants and their mothers were removed at once on notification to special hospitals; and the student in the general hospital did not get a chance of seeing cases. It was quite impossible to impress upon students the serious consequences of the disease unless they could be shown cases.

Mr. H. L. **Eason** corroborated Mr. Bishop Harman's remarks from his experience at Guy's Hospital. The disease had been extinct for several years in the school's maternity district, and cases which arose outside it were sent direct to an institution.

Dr. J. W. **Bone** thought that ophthalmia neonatorum should be removed from the group of "diseases of the eye" and considered as a "fever."

Mr. **Harman** said it had not been intended that the teaching of ophthalmia neonatorum should be withdrawn from its proper place in the curriculum, but the special hospitals where it was treated were regarded as fever hospitals. It had been proved to be a fever in order that the Metropolitan Asylums Board should make provision for it in a fever hospital. Hence the present problem.

The **President** said it was a matter for the schools. It should be easy for a teacher to make arrangements for his students to see these cases.

MEDICINE AND THE LAW

Prompt Notification of Accident

The Workmen's Compensation Act stipulates that an employer shall receive notice of a workman's accident "as soon as practicable after the happening thereof," unless it is found that the employer was not prejudiced by the want of notice, or that the want of notice was occasioned by "mistake, absence from the United Kingdom, or other reasonable cause." Naturally the workman's excuse for delay in notifying will usually be that he thought at first that his injury was trivial. This answer has been held insufficient in itself, though of course the decided cases turn each upon its own set of facts.

Here is a case recently decided by the House of Lords. In November, 1929, a 17-year-old workman injured his shoulder while employed in shifting pit-tubs for a colliery company. He mentioned his injury to a fellow-workman, rested several minutes, and finished his shift with assistance, then went home, told his mother, and lay down on a sofa. *According to his mother he became muddled in his* mind that evening, and was unable to get off the sofa, and so continued till he went to hospital in January. According to the doctor, who saw him on the day after his injury, the boy was rational and master of himself for three or four days, and seemed likely to be all right in a week. After four days the doctor diagnosed septic arthritis; the patient underwent nine operations in hospital owing to osteomyelitis, and came out a complete wreck in the following May. No notice of the accident was given before March, the boy explaining that he thought at first his injury was trivial. The county court judge found that (1) osteomyelitis developed after the injury which was therefore an accident; (2) the employers were not prejudiced by non-notification because no more could have been done for the patient than was actually done; and (3) the boy reasonably thought his accident was trivial at first, and afterwards was not in a condition to give notice; for these reasons the judge held that there was reasonable cause for the delay in giving notice. The Court of Appeal overruled this decision on the grounds that (1) notice was not given as soon as practicable, and there was no reasonable cause for the delay because the county court judge had accepted the doctor's evidence which showed that the workman was in a condition to give notice during the first few days; (2) the boy's belief that his injury was trivial was no excuse; (3) the employers were prejudiced in their defence by the want of notice because, the question being whether or not the osteomyelitis was latent *in the patient at the time of the accident*, it was vital for the employers to have had the chance to examine the workman as soon as possible after the injury. In confirming this decision the House of Lords has ruled that the employers were prejudiced and that there was no reasonable cause for non-notification. If the case seems a hard one, it was only reasonable for Parliament to enact, and only right for the law courts to enforce, the general principle that there should be facilities for prompt medical examination of the workman at the earliest possible moment.

Coroner on Osteopath's Treatment

At a recent inquest at Southend the deceased was reported to have had a dislike of doctors. He was attended by an osteopath. A medical practitioner e incident with which he is concerned. To the octor against whom the complaint is made it is nly one incident of many which probably happened n that particular day—e.g., one consultation or isit of many similar cases, and it is, of course, difficult r him to recall in detail precisely what happened, nless there was some salient point in the case. If, owever, his medical record is filled in with notes, uch as temp. 100·4 ° F.; resp., 36; pleuritic rub, t. base, it becomes very difficult for the patient to rove that the doctor did not take any interest in he case and hardly made any examination at all. he record moreover confirms the amount of ttendance given, often a matter of dispute between itnesses.

Failure to keep an adequate note of visits and ttendances is moreover not fair to other doctors, r quantitative extracts from doctors' records are ade usually on each inspection by the regional edical officer. He takes at random one letter of e alphabet and finds out the total attendance for e year on people whose names being with a particular tter. Suppose there are 50 record cards with names eginning with (say) B, there should be some 200 to 0 entries on all these cards; but if there are only 50 ntries present it appears that the doctor is only aying one visit or consultation per panel patient per ear instead of the usual (approx.) 4·5. The deficiency entry goes to swell the cost per attendance rate, aking the capitation fee appear too high, instead of ndicating the correct amount. Hence the failure keep accurate records is to be regretted in the terest of the insurance medical service as a whole, well as of the individual practitioner.

THE BIRTHDAY HONOURS

The list of honours issued on the King's Birthday ntains the names of the following members of the edical profession:—

K.C.M.G.

ieut.-General Sir John Goodwin, K.C.B., D.S.O., F.R.C.S.,
Governor of Queensland; formerly director-general of Army Medical Services.

K.B.E.

ing-Commander Louis Greig, C.V.O., M.B.,
Gentleman usher in ordinary to H.M. the King.

Knights Bachelor

enry Britten Brackenbury, LL.D., M.R.C.S.,
Chairman of Council, British Medical Association.

lbert Ruskin Cook, C.M.G., O.B.E., M.D.,
Senior physician, Mengo Hospital, Kampala, Uganda.

ieut.-Colonel Francis Edward Fremantle, O.B.E., F.R.C.S., M.P.,
Chairman of the Parliamentary Medical Committee; formerly medical officer of health for Hertfordshire.

olonel Richard Arthur Needham, C.I.E., D.S.O., F.R.C.P.,
Formerly deputy director-general, Indian Medical Service; lately inspector of medical education in India.

rthur Stanley Woodwark, C.M.G., C.B.E., F.R.C.P.,
Physician and dean of the medical school, Westminster Hospital; lately medical arbitrator for trades union and friendly societies insurance funds.

C.B. (Military Division)

ajor-General Henry Edward Manning Douglas, V.C., C.M.G., D.S.O.,
Deputy-director of medical services, Southern Command, India.

ir Vice-Marshal John McIntyre, M.C., M.B., K.H.S.,
Director of medical services, Royal Air Force.

C.B. (Civil Division)

Hamilton Clelland Marr, M.D., F.R.F.P.S.,
Senior medical commissioner, General Board of Control for Scotland.

C.S.I.

Brevet-Colonel Frederic Percival Mackie, O.B.E., F.R.C.P., K.H.S., I.M.S.,
Late director of the Haffkine Institute, Bombay, and formerly chairman of the Plague Expert Commission of the League of Nations.

C.I.E.

Colonel Harry Malcolm Mackenzie, M.B., I.M.S.,
Inspector-general of civil hospitals, Punjab.

C.V.O.

Commander Morton Smart, D.S.O., M.D., R.N.V.R.,
Formerly medical officer in charge of the electrical department, Hospital for Sick Children, Great Ormond-street.

C.B.E.

Percy James Kelly, M.B.,
Surgeon-general, British Guiana.

Russell John Reynolds, M.B.,
Physician in charge of the department of radiology, Charing Cross Hospital; adviser in radiology to the Ministry of Pensions.

O.B.E. (Military Division)

Temporary Major Ernest Kenneth Campbell, M.B. F.R.C.S., R.A.M.C.
Consulting surgeon, Western Ophthalmic Hospital; eye specialist, Southern Command.

Temporary Major Hugh Davies-Colley, B.Chir., F.R.C.S., R.A.M.C.

O.B.E. (Civil Division)

Rao Bahadur M. K. P. Avargal.
Director of the Tuberculosis Institute and superintendent of the Tuberculosis Hospital, Madras.

Seemampillai Francis Chellappah, M.R.C.S.,
Senior medical officer of health, Ceylon.

Andrew Connal, M.D.,
Director of the Medical Research Institute, Lagos, West Africa.

Ralph Stransham Oldham, M.D.,
Principal medical officer, Ministry of Pensions.

Hugh Brindley Owen, D.S.O., M.B.,
Medical superintendent and principal, Medical School, Mulago, Uganda.

Harry Chapman Sinderson, M.D., F.R.C.P.,
Dean and professor of medicine, Royal College of Medicine of Iraq.

Major David Rees Thomas, M.B., I.M.S.,
Chemical examiner to the Government of the Punjab.

Kaisar-i-Hind Medal (Bar)

Rai Bahadur Lala Mathra Dass,
Assistant surgeon to the Viceroy of India.

Ernest Muir, M.D., F.R.C.S.,
Research worker in leprosy, School of Tropical Medicine, Calcutta.

Kaisar-i-Hind Medal.

Mrs. Mary O'Brien Beadon, M.B.,
Principal, Lady Hardinge Medical College, Delhi.

Miss Helen Marion Franklin, M.B.,
Medical superintendent, Lady Reading Hospital, Simla.

Albert Hailey Henderson, M.D.,
Medical missionary, American Baptist Mission, Taunggyi, Burma.

Charles Edward Vail, M.D., F.A.C.S.,
Surgeon and physician, American Presbyterian Mission Hospital, Miraj, Bombay.

London and Counties Medical Protection Society.—The annual general meeting was held at Victory House, Leicester-square, W.C., on June 1st, when the President, Sir John Rose Bradford, moved the adoption of the annual report and balance-sheet. The work of the society, he said, was steadily increasing and many grave cases had come within its purview during the year. Some 800 new members had joined during that period, a large proportion of them immediately after qualifying, but he thought the increase ought to be still greater in view of the wastage by death and resignation. Dr. C. M. Fegen, late treasurer and chairman of council, was appointed to combine the offices of financial secretary and general secretary on the retirement of Dr. Hugh Woods.

PANEL AND CONTRACT PRACTICE

Complaints

The General Medical Council now receives official information of cases in which the Minister of Health has taken disciplinary action in regard to practitioners whose names appear upon the panel. We learn from the report presented by the solicitors of the London and Counties Medical Protection Society to the annual meeting on June 1st that members of that Society frequently require advice and assistance in difficulties and troubles arising out of practice under the National Health Insurance Acts. Complaints by patients to insurance committees are frequent, and when doctors concerned receive copies of the complaints made against them, with a request for their replies, it is of the utmost importance that the accusations should be effectively dealt with from the first. In the preliminary inquiries by the medical service subcommittees into complaints, legal representation is not permitted, but there is nothing to prevent a defence society from giving advice and assistance in the preparation of replies to complaints. These are of varied character, as the following examples will show:

A member applied to the Society in regard to the decision on an insurance committee suggesting that he should pay the account of another doctor who had been called in in his place and so dispose of the complaint against him. The matter was carefully gone into and the member was advised under the circumstances to make the payment as an act of grace.

A member complained to the Society that the local secretary of an approved society was in the habit of filling in the doctor's certificate form on a sick sheet, and signing the doctor's name. The matter was investigated and it was explained that the certificate was only a copy of a certificate given by the doctor. It was pointed out to the club secretary that he must in future mark the certificate clearly "copy," since otherwise it might lead to serious difficulties. The secretary promised to avoid the appearance of a forged signature in future.

A member wrote in regard to trouble which had arisen out of his marking a certificate with the diagnosis "I.D.K.," intended to indicate "Internal derangement of the knee," but which the approved society suggested must be meant to indicate "I don't know"—in other words, a negative diagnosis. He was advised that the letters "I.D.K." were not an adequate statement of the nature of the patient's ailment, although when compared with previous certificates it would be evident what diagnosis the letters were intended to indicate. A letter was drafted for him to the approved society and the matter was disposed of.

A member arranged for the removal of a very tiresome patient from his list and understood that her name had been removed. She called, however, upon him and insisted upon treatment, which he refused, as a result of which a complaint was made against the member. He was advised by the Society in the matter and the trouble was disposed of.

The Medical Defence Union in a report issued last year also impressed upon its members the need to consult the Union as early as possible in questions arising out of the National Health Insurance Acts. Although it is impossible for them to be represented at an inquiry before the medical service subcommittee, there is a stage earlier than this at which it is even more important that the assistance of a defence union should be secured. In cases of a complaint by an insured patient, the clerk has under the regulations to send on the letter of complaint to the practitioner and invite his comments upon it. Often the reply itself, if judiciously worded, and covering the essential points, will dispose of the matter and obviate the necessity for an inquiry, and it is upon this reply that members are advised to seek the Union's assistance. The solicitors to the Union point out that in appeals they have frequently been greatly handicapped by the injudicious nature of the practitioner's reply, in which he has either made unwise admissions or omitted to deal with essential points, thus providing food for telling cross-examination by the other side.

Prescribing in Manchester

A report presented by the clerk to the Manchester Insurance Committee shows the astonishing increase in the number of insurance prescriptions which pass through the pricing bureau. The increase has been going on in Manchester since 1917 when the number was 857,121, until 1927 when the number was 2,361,713. A drop took place then until 1930; but 1931 shows an increase of 78,704 over 1930, the total being 2,217,145 prescriptions. This gives a yearly average per insured person of 6·3 for 1930, and 6·4 for 1931; the cost per prescription remains the same, at 8·1 pence. For the whole country in 1930 the average was less than 3·7 prescriptions per insured person, little more than one-half the rate for Manchester. It would be interesting to know whether the attendance rate of Manchester doctors on their insured patients is also nearly double. The attendance rate for the whole country is known to be under five and above four, but the rate for Manchester has not been indicated separately. It will be remembered that with the close of 1931 the capitation system of medical benefit had been in operation in Manchester for only four years. Figures presented in this report show that in the last year of attendance basis (1927) the average number of prescriptions per insured person was 7, with an average cost per person of 5s. 3d. at drug tariff value, while on the capitation system the figures have gone down from 6·7 in 1928 to 6·4 in 1931, and from 4s. 10d. in 1928 to 4s. 3d. in 1931. The attendance basis of payment may be held to have been an incentive both to visit and to prescribe, but the maintained figures suggest either the faith of Manchester's doctors in drugs, or the determination of Manchester's insured persons to have them, unless indeed there is an extraordinary amount of ill-health needing medical attention.

A special return has to be furnished to the Ministry of Health upon prescriptions for insulin, serums, and vaccines. Of the vaccines the most costly were autogenous vaccines for 35 patients, costing £80 14s. 8d.; 75 patients received staphylococcal vaccine, costing £38, and 40 patients received anti-rheumatic vaccine, at the cost of £14 16s. 2d.

Medical Records

A leading article in the *Times* of May 16th, containing a suggestion that time, money, and temper are being wasted on medical records of panel patients, has called forth an able reply from Dr. G. C. Anderson, secretary to the Insurance Acts Committee. His letter, which appeared in the *Times* of May 21st, stated concisely and clearly what the obligations of insurance practitioners are, and how the system of records arose. Under present regulations records have to be kept, and a certain part of the capitation fee is always considered to be payment of this work. These records are often of great importance as evidence when charges are brought against a doctor of negligence, or even failure to visit. In all these cases from a memory point of view there is a great advantage to the patient as compared with the doctor, for sometimes a considerable number of weeks elapse before an investigation takes place by the medical service subcommittee, and in this time the complainant has written to the insurance committee, talked it over with relatives, and arrived at a definite impression of his story, which is, of course the dicitis, and as the importance of prompt treatment is recognised (delay in many cases costing the life of the patient), few nights pass without the resources of the hospital being taxed, and the already tired residents called upon to give up their well-earned rest and perform an operation.

I have taken the numbers from the St. Thomas's Hospital reports, from the records published yearly, with the exception of the war years which caused a gap, 1916 to 1920 inclusive. These yearly reports, which were first published in 1869, have followed a uniform plan, and many lessons can be learnt from them. The volumes issued before 1893 must engage our attention, although they are not included in this communication as part of the inquiry, which is intended to give the numbers of cases of recognised "appendicitis" admitted, but is not put forward with the view of showing conclusions other than the probable total of patients for this one hospital.

Many statements have been made as to the prevalence of appendicitis in this country. The publication of a book by Dr. H. P. Hawkins in 1895 on the diseases of the vermiform appendix did much to draw the attention of the profession to the fact that cases usually known before that time as perityphlitis were really cases of disease of the appendix. They were generally of a mild character, presenting an inflammatory mass in the iliac fossa, which rarely required operation, and then only a simple incision with drainage. The cases were always admitted to the medical side and the following are the numbers recorded :—

1873	4	1882	5	1889	18
1874	4	1883	5	1890	28
1878	2	1884	16	1891	24
1879	16	1885	8	1892	20
1880	5	1886	13	1893	28
1881	10	1887	12		

In the years 1869, 1870, 1872. 1880, 1881, 1882, 1883, 1885, 1886, 1887, 1888, 1889, 1890, 1891, 1892 there were between 1 and 13 cases of peritonitis, the number increasing somewhat as the years passed, but never more than 13 in one year. In the years not mentioned there were no cases of peritonitis having their origin in the appendix.

There was a change in the character of the disease about 1893, as proved by the evidence given in the hospital reports. There was usually a more severe onset, more frequent local suppuration which required incision, also more cases in which the inflammation was not limited to the iliac fossa, and where early operation was necessary. I have arranged the number of cases under consideration in groups.

(A) Patients suffering from appendicitis during the ten years 1894–1903—1075.[1]

These numbers include 48 patients who were admitted and treated on the medical side of St. Thomas's for perityphlitis, but which were undoubtedly appendicitis. On and after the year 1895 the word perityphlitis was no longer used. The gradual increase in admissions is shown as follows in selected years: 1895, 59; 1897, 90; 1899, 141; 1903, 163.

(B) During the years following 1904–1913 the numbers were considerably larger—3872. This increase will be best shown by giving the exact figures for each year :—

1904	258	1908	166	1912	552
1905	435	1909	328	1913	571
1906	332	1910	379		
1907	375	1911	476		

(C) The hospital reports were not issued for the years 1916–20 on account of the war, and the individual case reports are of doubtful value. But for the years 1914–1915 and 1921–1928 they are available and give a total of 3967 for the ten years.

(D) To the total may be added the numbers for 1929, which were 367.

The reports for 1930 have not yet been printed, but Mr. B. R. Sworn, surgical registrar, has kindly sent them to me and they amount to 200, making the total for St. Thomas's in the period 1894 to 1930, excluding the war years, 9481.

It must be remembered that these figures can only be comparatively correct, for in more recent years a new section of "abdominal pain" has appeared. In a majority of these the cause of the pain was "not proven." During one year these cases numbered 80. The admission of urgent cases of appendicitis during the war years was not in any way checked.

Thinking that it might be useful to compare the numbers treated in a recent year at other large hospitals, I made application to Guy's, St. Bartholomew's, and the London, and selected the year 1930 as most convenient to compare with those of St. Thomas's.

I have received replies from Guy's Hospital (392) and St. Bartholomew's (329), for which I thank Mr. C. E. Hughes and Mr. Girling Ball respectively. I hope to be able to add the return from the London Hospital at a later date.

I am, Sir, yours faithfully,

Harley-street, W , June 1st, 1932. W. H. BATTLE.

FORLANINI AND HIS FOLLOWERS

To the Editor of THE LANCET.

SIR,—I have recently heard from Prof. U. Carpi, of Milan, general secretary of the International Society of Pneumothorax Artificialis. He desires that it should be made public in this country that the objects of the society have been altered and that one of them is the raising of a monument in Rome in memory of Carlo Forlanini.

The International Society of Pneumothorax Artificialis was founded in 1912 and strove to diffuse knowledge and facilities about collapse therapy amongst physicians of the world. It also aimed at providing periodically for the sick a list of doctors who practised pneumothorax. Since this method of treatment is now so widely acknowledged and followed in all countries of the world it has been decided to reconstitute this society. All interested physicians are asked to write periodically to the general secretary so that he may be able to publish an up-to-date bibliography of books and articles on collapse therapy in the society's periodical bulletin. He also wants to receive for similar publication communications about pneumothorax instruments and methods of technique, notes from the inventors of these, and brief reports on congresses devoted to collapse therapy.

Prof. Carpi appeals for subscriptions for the monument to Forlanini not only from doctors in this country but also from any patient who has gained health by the method of artificial pneumothorax. I have no doubt therefore that you will allow space for this letter to advertise these laudable objects. Forlanini's pioneer work deserves wide recognition.

Prof. Carpi's address is Via Alberta da Guissano 18, Milan. I am, Sir, yours faithfully,

S. VERE PEARSON.

The Sanatorium, Mundesley, Norfolk, June 2nd, 1932.

CORRESPONDENCE

APPENDICITIS

To the Editor of THE LANCET.

SIR,—I was rather astonished by a good deal in Sir James Berry's oration on Fallen Idols, but some of the correspondence which has arisen out of this paper seems to me lamentable; I refer particularly to a letter in THE LANCET of June 4th by Mr. Paterson. Here, if I understand him rightly, he suggests waiting until the appendix has perforated in order to get a clear indication for operation; and even when this catastrophe has occurred he likes to spend several hours giving saline, glucose, and sodium bicarbonate, with the hope that symptoms will subside. I cannot think what grounds he can have for taking this line. The mortality of the operative treatment of acute appendicitis, whether we regard it as acute inflammation or acute obstruction, is nil or as near it as makes no matter, when appendicectomy is performed within a few hours of onset. After the occurrence of such complications as perforation, abscess, &c., the operative mortality is in the neighbourhood of 7 per cent. In the small number of cases mentioned by Sir James Berry expectant treatment had a mortality of 4 per cent., and I should think a larger series would show a mortality of at least 7 per cent. Where, then, is the justification for preaching delay, for that is what Mr. Paterson does? Is it not obvious that the ideal treatment is operation within a few hours of onset, and is it not our business to go on trying to achieve the ideal?

In practice this is difficult, and those who take up Mr. Paterson's attitude make it more so; attempts to encourage this attitude of mind are, in my opinion, most pernicious. If Mr. Paterson had merely said when an appendix had perforated and the trouble had been localised, or general peritonitis had developed, he would wait before advising operation, relying rather on expectant methods because the mortality of operative treatment is as high as that of the other, I think he would have had the support of some surgeons at any rate, but when he advocates deliberately (as he seems to do in his letter) the policy of "wait and see" if such things arise before removing the dangerous focus (and after all who can prophesy what will happen?) I can only hope, as I firmly believe, he will receive no support whatever from right-thinking surgeons.

I agree with Prof. Wilkie that pure acute inflammation of the appendix and pure acute obstruction of it are two different things and of the two the latter is the more immediately dangerous; but they often coexist, and if a patient presents the symptoms and signs of an acute inflammation of the appendix, when first seen, it is utterly unsafe to suppose he has not an obstructive lesion of the organ too, which is therefore unlikely to perforate. It is quite a common thing to find an acutely inflamed and obstructed appendix at the time of operation very near the point of perforation. I am, Sir, yours faithfully,

Leeds, June 4th, 1932. E. R. FLINT.

To the Editor of THE LANCET.

SIR,—May I, as a general practitioner, and therefore one of those upon whom the general public must mainly depend for any reduction in the still appalling mortality from appendicitis, trespass upon your space with a plain-spoken letter? I first was aware of Sir James Berry's lecture entitled Fallen Idols from the excerpts in the lay press. They made, and could only make, one impression on the reader and that was (1) that in the opinion of the lecturer a large number of people died yearly as the result of unjustifiable operative interference, and (2) that if death was to be avoided in appendicitis all that need be done was to await the arrival of a nice abscess, which could be safely opened and drained. When my LANCET arrived later and I read Sir James's article in toto, I found it was innocuous and even contained some sound and sage reflections. It was, in fact, a very suitable lecture with which to open a debate; but in my opinion a dangerous and retrogressive piece of rhetoric when delivered, as it was, on an occasion when it was sure to be broadcasted to the public at large.

Speaking generally the criticisms it contained were entirely destructive and no help was given to young practitioners to enable them to decide when it was safe to wait and when it was dangerous to do so. Personally I do not think any written or spoken word, or even demonstration, will enable a learner to decide. As always, "experience teaches"; but if we are to bring down the mortality of appendicitis to the irreducible minimum of deaths (and deaths in appendicitis need and should only be due to such relatively small and possibly unavoidable causes as anæsthetic deaths, deaths due to embolism, intestinal obstruction, mechanical or paralytic, and so forth) there must be only one teaching, and that the simplest—namely, to operate at once and on suspicion. Pain in the iliac fossa that is accompanied by any degree of tenderness justifies operation. The formation of an abscess ought to be looked upon as a disgrace It is better occasionally to remove an apparently healthy appendix, than to lose one patient's life from taking the risks of delay.

I am prompted to write this letter as a set-off to the eulogistic letters already published. I consider that Sir James Berry has confused and not clarified the situation, and has made things more difficult for the general practitioner in having done something towards biasing the lay mind against operation. If the mortality from appendicitis is to be reduced, it can only be done by clear and simple rules for treatment being enunciated by our teachers. Let us admit frankly that in the earliest stages we do not know in the least what is happening and that there is only one way to find out: Look and see.

I am, Sir, yours faithfully,
LEONARD LEY, M.B., B.Chir. Camb.,
Hon. Surgeon, Great Yarmouth Hospital.
June 4th, 1932.

APPENDICITIS: A FIFTY YEARS' EXPERIENCE IN ST. THOMAS'S HOSPITAL

To the Editor of THE LANCET.

SIR,—In a correspondence in your issue of May 21st, arising out of Sir James Berry's address to the Medical Society of London, a letter from me was included in which I expressed no view on the question of delayed operation in appendicitis, but suggested that an investigation into the increasing incidence of the disease should be undertaken.

In urging on the profession the importance of an inquiry into the causation of appendicitis, it has seemed advisable to give some figures showing the tax which these cases have been on the hospitals of London and the staffs who are called upon to treat them. It is quite unusual in a large general hospital for a day to pass without one operation for appen-in official requirements, and of making the necessary arrangements to meet them.

Every person who takes advantage of this opportunity will be expected to observe the conditions above indicated, and will be required to sign an undertaking to that effect. Inquiries by letter or telephone cannot be answered.

I am, Sir, yours faithfully,
NORMAN C. KING,
Registrar, General Medical Council.
44, Hallam-street, London, W.1, June 4th, 1932.

UNDULANT FEVER

To the Editor of THE LANCET.

SIR,—In view of the interest taken in undulant fever, and the work of Dr. C. P. Beattie and others, recently published in your columns, perhaps the following figures of *Br. abortus* incidence in milks in this area may be of interest. Between 1927 and 1931 I examined for the presence of *abortus* agglutinin the sera of 760 guinea-pigs inoculated in this laboratory with milks (primarily for T.B.). The following are the results:

170 showed *abortus* agglutinin at 1 in 40 or higher = 22·3 %
145 „ „ „ 1 „ 80 „ = 19 %

Roughly therefore 20 per cent. of these animals showed that they had been infected with *Br. abortus*, but as the milks were nearly all mixed samples the positive percentage might actually be higher.

Unfortunately I have but a small number of controls—i.e., animals used for other purposes than milk inoculation. None of these showed a trace of *abortus* agglutinin. Brucella was repeatedly isolated from the glands, spleen, and heart blood of the animals showing *abortus* agglutinin. Milk whey frequently shows the presence of *abortus* agglutinin, but this is no evidence of the actual presence of brucella in such milks. In a small number of whey-positive milks I found just under half (45·4 per cent.) which gave no evidence of infection in the guinea-pigs inoculated.

During the above period I examined 650 human sera for the presence of *abortus* agglutinin. I found it in six cases:

Once 1 in 20 only.	Twice 1 in 80
„ 1 „ 40	„ 1 „ 160

None of these persons was suffering from any disease resembling undulant fever, and in only one case was there any history at all suggestive of a previous infection.

I am, Sir, yours faithfully,
A. H. PRIESTLEY,
Bacteriologist to the Burnley Corporation.
May 31st, 1932.

TREATMENT OF LATE RICKETS AND OSTEOMALACIA

To the Editor of THE LANCET.

SIR,—Dr. D. C. Wilson's finding that certain cases of osteomalacia in Northern India are benefited by the administration of tricalcium phosphate is in line with my experience in the treatment of this disease in the Mayo Hospital, Lahore.

It was found that in some patients (none of whom had ever observed purdah), improvement was very slow or at times non-existent under treatment with vitamins A and D and sunlight, and it was assumed that the diet taken by these individuals did not contain sufficient calcium and/or phosphorus. During the past 18 months or so I have therefore been including calcium glycerophosphate in the treatment of all osteomalacic patients[1] and the results have been beneficial, especially in the resistant cases. The usual daily dose is grs. 30, but sometimes larger amounts, up to grs. 60 daily, are given. Whatever the initial state of the blood chemistry, which varies in different patients, improvement is always associated with a normal serum calcium and a serum inorganic phosphorus as high as that found in healthy infants and young children.

It may be of interest to mention that the daily ultra-violet solar radiation in Lahore in the cold weather was found to be from 3 to 8 units by the acetone-methylene-blue gauge, the average being about 5. In the highlands of Kashmir, a State in which osteomalacia is prevalent, from 8 to 16 units a day were recorded. The occurrence of the disease in non-purdah individuals living in these regions may therefore be, to some extent, the result of a deficiency of calcium and/or phosphorus in the diet.

I am, Sir, yours faithfully,
T. A. HUGHES, M.D., M.R.C.P.,
Professor of Clinical Medicine, Medical College, Lahore.
Bexhill, May 30th, 1932.

FREE TREATMENT AT VENEREAL CLINICS

To the Editor of THE LANCET.

SIR,—With a practical experience of over 20 years in venereal diseases, I heartily endorse all that Dr. Wansey Bayly asserts in his letter to you. It is time that some committee should be set up to review the whole position. The very object for which the Government voted large sums of money has been defeated. All and sundry flock to the clinics without fear or favour. Modern youths have no knowledge of the deterrents to promiscuous intercourse that their fathers realised, with the result that instead of diminishing the incidence of venereal diseases is rising. As Dr. Bayly states, the venereal specialist is facing ruin—and for whose benefit?

I am, Sir, yours faithfully,
London, W., June 4th, 1932. M. W. BROWDY.

To the Editor of THE LANCET.

SIR,—The adoption of the points of view expressed in the letter of Dr. Wansey Bayly would undoubtedly lead to anti-social interference. If there is a group of infectious diseases whose ravages are not limited to any one section of the community, that group, beyond question, is the venereal. It is true that venereal disease is preventable, but adequate prophylactic teaching is not yet carried out—not even to the extent of instruction of students of medicine. Therefore, until this education is widely instituted, venereal disease cannot be said to be "voluntarily" acquired.

Dr. Bayly confuses two aspects of medicine: (1) the treatment of disease; (2) the income of doctors who make a living treating it. With regard to the first, it is in the interests of the nation that venereal disease be wiped out; and for this simple human work treatment should be free. The second aspect can lead to alarming implications. For, carrying this to its logical conclusion, we come to the unavoidable position that it is in the interest of venereal specialists that venereal disease should not be exterminated. I do not suggest that doctors are guilty of wishing for this state of affairs, but it seems to me that we should resist any attempt to limit

DIPHTHERIA IMMUNISATION IN INFANTS

To the Editor of THE LANCET.

SIR,—In an interesting annotation in your issue of June 4th (p. 1210) you discuss the above important question. As regards urban districts, where about 85 per cent. of children are born with maternal diphtheria antitoxin in their blood, the conclusions arrived at in the annotation appear sound. I would point out, however, that in rural districts 70 per cent. or more of the adults may have positive Schick reactions. This means about the same proportion of infants are born with no antitoxic immunity to diphtheria. In the rural state of Kansas, for example, a most successful anti-diphtheria campaign, among the children of 1 to 14 years of age, was followed by an actual rise in the morbidity and case-mortality for diphtheria among the unprotected infants under a year old. In such districts it would appear very necessary to protect infants at birth. Two methods of procedure suggest themselves:—

(*a*) Schick testing the mothers, and immediately immunising the babies of those who have positive reactions. Schick testing the babies themselves is probably less reliable, because the infants' skin is often relatively insensitive to bacterial toxins, and may fail to react to the ordinary Schick dose of diphtheria toxin, even when there is no antitoxin in the blood. The infants, whose mothers are Schick immune, are actively immunised as usual, after they have lost their maternal diphtheria antitoxin.

(*b*) Inoculating the mothers with diphtheria toxoid during their pregnancy. The maternal diphtheria antitoxin, thus stimulated, will pass to the fœtus. Subsequently the babies themselves are actively immunised after they have been born 12 months or so.

The latter method is analogous to that said to have been used successfully in preventing umbilical tetanus, common in certain tropical regions. In this campaign the pregnant women were inoculated with tetanus toxoid. I am, Sir, yours faithfully,

SHELDON F. DUDLEY.

R.N. Medical School, Greenwich, S.E., June 4th, 1932.

AVERTIN NARCOSIS

To the Editor of THE LANCET.

SIR,—The statement made by Dr. Kennedy in his communication on the Counteraction of Avertin Narcosis (THE LANCET, May 28, p. 1143) that lavage of the rectum is of no avail needs to be modified. It is true that the absorption of avertin is extremely quick—this is one of its many advantages—but I have noticed that on those occasions on which the solution has been returned even as late as half-an-hour after injection, or on which it has been deliberately syphoned off, for example, before the performance of a plastic operation on the perineum, there has been a definite diminution in the depth of narcosis. In one case of extreme overdose (10 times) reported to me, which occurred owing to a little difficulty with those "dashed dots," washing out the rectum was effective, and the operation was completed without mishap or complication.

Raginsky and Wesley Bourne have published the results of experiments on dogs which show that ephedrine interrupts or considerably shortens avertin anæsthesia (*Jour. Pharm. and Exper. Therap.*, 1931, xliii., 209). They have demonstrated also the value of ephedrine clinically in overcoming profound avertin anæsthesia. Dr. Kennedy's communication draws attention to another line of defence. The necessity for the use of either of these drugs should be extremely rare, for by restricting the use of morphia to suitable cases and by individual dosage the risk of overdose should be abolished.

I am, Sir, yours faithfully,

FRANCIS E. SHIPWAY,

York-terrace, Regent's Park, N.W., June 6th, 1932.

HÆMORRHAGIC PURPURA FOLLOWING SCARLET FEVER

To the Editor of THE LANCET.

SIR,—It has been brought to our notice that some who have seen our paper on Hæmorrhagic Purpura following Scarlet Fever in THE LANCET of March 5th (p. 509) have read into it a meaning that was neither intended nor implied—namely, that some tendency must be assumed to exist in the family that might conceivably affect other members.

In this family there has been hitherto no hæmorrhagic or purpuric disease within memory, and no disease in earlier generations could have been overlooked, for detailed knowledge is available of most of its members as far back as the early years of the eighteenth century.

Out of 18 references to other cases quoted in our paper, in 11 the possibility of hereditary and familial abnormalities was not thought important enough to mention. In seven others the family history was negative to any history of bleeding, purpura, or tendency thereto. In the paper reported by J. W. Miller (THE LANCET, 1905, i., 929) it is stated that two other brothers who developed scarlet fever at the same time as the patient who suffered from purpura had since recovered from the disease without any similar complication.

It is therefore clear that while in our case two members of the same family were affected, there is no logical ground for assuming that there is any hereditary or familial tendency towards this condition so far as previously reported cases are concerned.

We are, Sir, yours faithfully,

F. G. HOBSON,
A. G. GIBSON.

Oxford, May 31st, 1932.

THE NEW PHARMACOPŒIA

To the Editor of THE LANCET.

SIR,—The new issue of the British Pharmacopœia (1932) will be published on Sept. 30th, and I am instructed to say that the General Medical Council wholly reserve their copyright in the new work, and that nothing in the nature of substantial extracts from it must be published without the Council's express sanction. A memorandum relating to this matter in detail can be supplied on application. At the same time no objection will be taken to such reasonable reference to the facts and figures therein set forth as may be properly made for purposes of criticism, review, and summary, or of study and research, but no information of any kind derived from the new issue may be published in book form before Sept. 30th.

Advance copies of the text of the Pharmacopœia will be accessible on July 4th, at this office, and at 12, Queen-street, Edinburgh, and 35, Dawson-street, Dublin, for the inspection of the public, from 10 A.M. to 1 P.M. and from 2 P.M. to 4 P.M. daily excluding Saturdays, in order to give to manufacturers, pharmacists, and others interested an opportunity of ascertaining the changes that are about to be made

PUBLIC HEALTH SERVICES

SCOTLAND IN 1931

THE third annual report of the Department of Health for Scotland follows the form laid down by the Board of Health in 1924. Indeed, the series from then onwards presents material for a valuable study of the evolution of health functions in a small kingdom.

The year 1931 was dominated by unemployment and the need for economy. These, in association with the extensive reorganisation involved in the new Local Government Act, made the period a difficult one; but the report shows how the work has gone on smoothly and systematically.

Housing has made progress, although the year's output of completed houses was only 10,604 as against the record of 18,240 of 1929. But there were at the end of the year 20,196 houses under construction or approved, and 1932 promises well. The falling off was very natural, since local authorities get "saturated" from time to time and changes of methods and governments tend to interrupt progress. But the Department clearly means to press the new housing and slum-clearing legislation and the velocity of production will probably be soon restored. The number of houses provided, with State assistance, between 1919 and 1931 was 128,007; and by private enterprise without subsidy 14,262. The total is 142,269.

Maternal mortality shows a drop from 6·9 per 1000 births to 5·9. Infant mortality, which stood at 129·4 per 1000 births in 1896–1900, was 85·5 in 1926–30. But these figures are still disappointing. Puerperal sepsis and puerperal pyrexia show signs of being better notified: 1104 and 1053 cases respectively. Of the 1177 puerperal fever and 906 of pyrexia notified in 1930, 863 and 358 respectively were removed to hospital. Greater advantage was taken of the assistance provided by local authorities in such cases—consultants, bacteriological examinations, special nursing, and hospital-treatment. Postnatal applications at the welfare centres by mothers were mainly due to insufficiency of breast milk and to the child being under weight. "An examination of the applications granted free in Glasgow during 1930 showed that more than one-half of the applicants were in receipt of unemployment benefit."

Health supervision of the pre-school-children (1–5) shows much improvement, 71,048 being visited on an average four times each. But the total number of children in this group is about 340,000. One striking fact emerges as to the school group (5–15). The Glasgow report (reviewed below) shows that there is an increase in the heights and weights of boys and girls in each age-group according to the size of the house they live in. This confirms the report issued by the Scottish Education Department in 1907 on the heights and weights of 72,857 Glasgow children.[1] But there is a new fact about the ages 9 and 13; for in 1931 the average heights and weights of the children at those ages from one-apartment houses exceeded those of the children from two- and three-apartment houses in 1907. "That school entrants do not show quite so much relative improvement suggests the beneficial influence of modern school life."

A fresh statistical analysis of tuberculosis has been made as a first step in the investigation of the geographical incidence of tuberculosis in Scotland, with correction for age constitution of the area populations. The facts presented deserve further elaboration.

A feature of this year's report is the account of hospital reorganisation. Illustrations are given of the successful efforts to bring official and voluntary hospitals into coöperative unity. Another feature is the large results of the administration of the Highlands and Islands Medical Service Fund. This is working a transformation on the medical and nursing services. The most striking departure has been taken by the county of Caithness.

> In Caithness the county council "acts as the financial authority for the surgical arrangements, while the surgeon performs all the surgical duties required in the county, in both the voluntary and the statutory hospitals. When called upon by general practitioners, he also acts as surgical consultant in the houses of the people. It has been arranged that the department will repay the council one-half of the charges incurred under the financial guarantee after deduction of sums recovered as fees for the surgeon's services."

These arrangements are interesting in themselves; the following, however, is, so far as we are aware, unique in this country. When consultant surgeons were first appointed (1924) in Shetland and Lewis, it was felt that an effort should be made to conserve the "placings" of young surgeons sent to those outposts; but, at that date, the difficulties were too great and there was no experience of the new departure. But Caithness county, along with Aberdeen, has solved the problem.

> "With the concurrence of the University Court and the managers of Aberdeen Royal Infirmary, the professor of surgery at Aberdeen University nominated a surgeon for a limited period of duty in Caithness, whose prospects in relation to the University and the Infirmary will not be diminished by reason of his service in Caithness. If, as vacancies occur elsewhere, surgeons could be appointed in this way so as to retain their status at medical teaching centres, anxiety as to the future of this specialist service in Highland counties would disappear. The sympathetic consideration given to the problem by the Court of Aberdeen University and the managers of Aberdeen Royal Infirmary, which has produced the practical scheme under which surgical services are now being provided in Caithness, is deeply appreciated by the Department."

And we may add that the Department is to be congratulated on a new departure of no little importance.

SCHOOL MEDICAL SERVICE

Derbyshire

THERE are apparently no special schools of any kind in Derbyshire (except the excellent hospital school), no nursery schools, and no open-air schools, nor have comprehensive arrangements been made for playground classes, school journeys, or open-air classes in elementary schools. The County Education Committee has offered assistance to 308 needy children to attend the many camps organised by the Voluntary Camping Association. Fourteen of the 377 elementary schools are of the famous Derbyshire open-air type, but they are not open-air schools in the full meaning of the term. To what extent these defects could be rectified even at the present time needs careful consideration. Dr. W. M. Ash says that the economic position has made it impossible to contemplate any marked extension in the service.

the present services for the treatment of venereal disease. On the contrary, we should extend them, and really make an effort to attack venereal diseases scientifically, that is, by propagating widespread information of prophylaxis for these social plagues. The abolition of venereal disease by planned measures on preventive lines should afford us pleasure which would adequately compensate for the sorrowful picture Dr. Bayly draws for us of. the venereal specialist seeing ruin staring him in the face.

I am, Sir, yours faithfully,

FRANCIS LOUIS.

St. Peter's (Whitechapel) Hospital, E., June 5th, 1932.

THE SHUTTLEWORTH SAMARITAN FUND

To the Editor of THE LANCET.

SIR,—May we ask for the hospitality of your columns in order to make known, to all who have the welfare of the mentally defective at heart, that a fund is being raised to form a memorial to the work of the late Dr. G. E. Shuttleworth?

It is now nearly four years since Dr. Shuttleworth passed away, after a long life devoted to the welfare of the mentally defective, in which cause he was a pioneer. It is proposed that the memorial should take the form of a Samaritan Fund, named after Dr. Shuttleworth, which should be available to help better-class people to place their children or relatives in appropriate homes for care or training. Families of this class are prevented by many considerations from applying for aid to public assistance authorities, nor, in their case, even when such help is sought, is it easily obtainable. No other fund of the kind exists, although in many cases under post-war conditions, such help as it would offer has become essential. It is felt that this would be a particularly happy way in which to commemorate the work of one who was ever ready, with a singular generosity, to give his advice and aid to all who were in need.

Donations of £115 have already been received, and it is thought that many will be glad to have this opportunity to show their appreciation of Dr. Shuttleworth's great and unselfish services. Subscriptions should be sent to the treasurer, the Shuttleworth Samaritan Fund, 72, Denison House, 296, Vauxhall Bridge-road, S.W.1, or direct to the Shuttleworth Samaritan Fund, Martin's Bank, 68, Lombard-street, E.C.3.

We are, Sir, yours faithfully,

(Signed) G. A. AUDEN,
F. G. CROOKSHANK,
T. N. KELYNACK,
R. LANGDON-DOWN,
W. A. POTTS.

THE KING'S COLLEGE HOSPITAL SCHEME

To the Editor of THE LANCET.

SIR,—As a practitioner who has to earn his livelihood in the area served by King's College Hospital, I am entirely in sympathy with the remarks of THE LANCET (May 28th, p. 1172) on the scheme of contract practice inaugurated by this hospital for persons of unlimited means. In its initial stages the scheme took no notice at all of the general practitioner. Anyone with an income of thousands a year taken with a suitable pain in his abdomen could go to King's on his own account and because he had paid £11 per year to the hospital his appendix would be removed in a paying ward without charge by the hospital and at a reduced fee by the surgeon, without his ordinary medical attendant even hearing of the matter unless the patient should come to him later with a ventral hernia. Now, however, I observe an amendment to the rules that runs: "Normally patients will only be admitted on the advice of their own doctor." Not a very strong safeguard, nor really of much help to the practitioner. It does seem a pity that young consultants should not stick to consultant work, and I am convinced that the only effective method of dealing with the situation would be to notify all local medical organisations of the position, and for them to advise that no cases be sent to any consultant who is prepared to act in the way suggested.

I am, Sir, yours faithfully,

R. GODWIN CHASE, M.B., B.Chir.Camb.

CHLOROFORM AND THE HEART

To the Editor of THE LANCET.

SIR,—Might I suggest that Dr. I. G. W. Hill should examine electrocardiographically patients under light chloroform anæsthesia to whom a preliminary dose of atropine gr. 1/60 has been given one hour before. I have been giving chloroform to patients for the last 24 years at the Manchester Skin Hospital. These patients have, practically speaking, never been deeply anæsthetised. The majority of them move when the operation commences. During that time I have seen three cases of early chloroform collapse, that is pallor, sweating, dilated pupils, respiration so shallow as to be doubtfully perceptible, pulse so feeble as to be doubtfully palpable. Fortunately they all recovered. The interesting point is that none of these three had had a preliminary dose of atropine. I found this out on inquiry after. In each case it had been forgotten. It has been my routine practice to give a preliminary dose of atropine to all my patients whether they were to receive ether or chloroform, since 1910. From the clinical standpoint I have seen no evidence which would lead me to suppose that ventricular fibrillation is ever a cause of death in patients under light chloroform anæsthesia if they have had a preliminary dose of atropine. Actually, in practice I use morphia as well as atropine, but I have always supposed that it was the atropine that safeguarded the heart from vagus inhibition, which latter is, in my opinion, the precursor of ventricular fibrillation.

I am, Sir, yours faithfully,

E. FALKNER HILL,
Lecturer in Anæsthetics in the University of Manchester.

Manchester, June 6th, 1932.

GLASGOW'S NEW DENTAL HOSPITAL.—Last week Sir Ian Colquhoun, Lord High Commissioner of the Church of Scotland, paid a semi-state visit to Glasgow as representing the Prince of Wales to open a new dental hospital in Renfrew-street. This is the first time in nearly 300 years that a Lord High Commissioner, in that capacity, has visited Glasgow. The hospital, which includes a training school, is said to be "the most modernly equipped dental hospital in Britain." There are 50 dental chairs with provision for a further 22, and eight children's chairs. In addition to an X ray department there is a pathological and histological laboratory *with accommodation* for 50 students. A large theatre for general anæsthetics has recovery cubicles for men and women. The lecture theatre has sitting and writing accommodation for 200 students; two smaller lecture rooms will each hold 50 students, and there is a library and museum. The cost has been £65,000, of which £27,000 has yet to be raised.

OBITUARY

REMINGTON HOBBS, M.D. Brux., M.R.C.P.Lond.

Dr. Albert Remington Hobbs, who had been medical superintendent of St. Mary Abbot's Hospital, Kensington, for some 15 years, died on May 30th after a serious operation. He was at work less than a fortnight before his death.

Remington Hobbs was trained at St. Mary's Hospital, whence he qualified M.R.C.S., L.R.C.P. in 1901, becoming M.R.C.P. in 1930. He took the M.D. Brux. with honours in 1908. After qualifying he held appointments at St. Mary's Hospital as house surgeon, house physician, resident obstetric officer, casualty officer, and resident anæsthetist. He worked also for a time as assistant demonstrator of pathology and as ophthalmic house surgeon at St. Mary's, and as clinical assistant to St. Peter's Hospital and to the Paddington Green Children's Hospital and the Samaritain Free Hospital. Dr. Hobbs had thus gained exceptionally wide experience before his first administrative appointment as assistant medical superintendent to the Paddington Infirmary. He held this post until 1907 when he started general practice in Golders Green. On the outbreak of the war he left his practice at short notice to serve in the Army. He was, however, soon invalided out, and held the post of medical superintendent at Bethnal Green Infirmary before being appointed in the same capacity to St. Mary Abbot's Hospital, Kensington, where he became well known especially in connexion with the treatment of puerperal sepsis. He first became interested in the subject 13 years ago, and eventually worked out a line of treatment which proved extremely successful in his hands. This was based on his conviction that puerperal sepsis is, for the most part, an autogenous infection superadded to imperfect drainage. He showed that latent bacilluria is common in pregnant women, that puerperal sepsis can exist without pyrexia, that after-pains are abnormal and significant of sepsis, and finally, that with perfect drainage brought about by intra-uterine injections of glycerin many cases are cured. He believed that in many of the more serious streptococcal infections early uterine drainage would prevent the spread of infection and a general septicæmia. So enthusiastic was he in this special work that he started a clinic for teaching his methods, and during the last ten years medical men from almost every country in the world have attended his demonstrations. His methods were not at first generally accepted, but his enthusiasm remained undiminished and it was a source of great satisfaction to him in recent years to find a growing interest among gynæcologists in his work. He rejoiced at his appointment as Hunterian professor of the Royal College of Surgeons for 1932, as giving him an opportunity to give further publicity to his methods. Three days after his fatal illness began he was awarded the Triennial Gold Medal of the West London Medico-Chirurgical Society for distinguished work, and the news of this honour greatly comforted him during his last few days of life. In addition to his official appointment at St. Mary Abbot's Hospital, he was consulting gynæcologist to the Royal Borough of Kensington. This appointment was welcomed by the medical profession in the district, for he had their entire confidence.

ALBERT REMINGTON HOBBS.

A colleague writes: "Remington Hobbs was not only a medical man keenly interested in the specialty he had made his own, but also a splendid sportsman. He and his brother (E. C. Hobbs) were for some time the first wicket batsmen for St. Mary's Hospital, and Remington made a fine century against St. Thomas's when St. Mary's won the Hospital Cup in 1899. With his brother he put on 104 runs for the first wicket when playing for St. Mary's against Dr. W. G. Grace's London County Eleven in 1900. Afterwards he played for the Middlesex Second Eleven and for some years for Buckinghamshire, and he was playing in London club cricket and making good scores until two years ago. Hobbs was a lovable person and a delightful companion. He was so good natured, so kindly, that it was difficult to differ from him. His home life was particularly happy, and much sympathy will be felt for his widow and his two boys."

Dr. Leonard Colebrook writes: "It says much for his enthusiasm and industry that Remington Hobbs, while carrying all the cares of a large poor-law infirmary, was able to make a name for himself as the advocate of a particular form of treatment. Instillation of glycerin into the infected uterus had occasionally been tried in the past, but had not attracted special attention. Indeed, at the time (1920–23) when Hobbs became interested in the puerperal infections almost every remedy had become largely discredited. Inspection of the genital tract to determine what was the condition of the cervix and vaginal vault was seldom made, and if there was obstruction to the outflow of the discharge through the cervical canal, it was scarcely ever recognised. To Remington Hobbs, more than to any other man, is due the changed attitude with regard to this condition. He recognised that drainage, both of the uterine cavity and of the infected tissues, was a vitally important factor in recovery, and that the application of glycerin was likely to facilitate such drainage. Having satisfied himself that dramatic improvement in the patient's condition did frequently follow the instillation of glycerin he set himself to perfect the technique of the operation so that it could be carried out, if necessary, several times a day without undue pain or discomfort for the patient. It is not too much to say that he set up a new standard of skill (and of gentleness) in the examination and treatment of the patient with a postnatal infection. Not content with the improved results in the cases of established infection admitted to his hospital, he worked unceasingly by the same methods to control the mild pyrexias in his own maternity department—and also to bring the success of the 'glycerin treatment' to the notice of others.

The dental attendances have greatly increased and the staff, working at full strength, has just been able to cope with the work. Progress is largely due to the increasing interest taken by parents in conservative dentistry. In certain areas statistics showed that where the percentage of consents for conservative dental work was high, the percentage of cases requiring a general anæsthetic was low, and vice versa, and here, as in many other areas maintaining an efficient dental service, the interference with routine caused by the casual patient was much felt. A striking illustration of the importance of oral hygiene is given: Out of 540 children referred by assistant school medical officers for dental treatment prior to tonsillectomy or prior to a period of observation for enlarged tonsils, 444 had previously refused dental treatment or were school entrants. This finding reinforces Dr. Ash's plea that whenever possible conservative methods, including dental treatment, should be tried before tonsillectomy is carried out.

Dr. T. E. A. Carr, the oculist, points out that while tests of refraction and the provision of glasses increase the patient's comfort and efficiency, the treatment of conditions such as corneal ulcers and early cataracts is even more vital since it may prevent actual blindness. The early treatment of squint is also of paramount importance in the preservation of vision. Of the three lines of attack, (1) correction of refractive errors, (2) orthoptic exercises, and (3) operation, orthoptic exercises are difficult and costly to provide, and yet for the real cure of squint the training of the latent fusion faculty is fundamental. The orthopædic scheme, including the special hospital at Bretby, is functioning well. A full report on postural defects by Dr. W. J. Pierce has had to be condensed; he points out the insidious onset of postural deformities, the ease with which most of them can be corrected by treatment in the early stages, and the difficulties of treatment if it is postponed until deformity has become marked.

The principle of early detection and correct treatment that is the keynote of the report is exemplified in Dr. H. S. Bryan's account of the work of the Child Guidance Clinic.

Eastbourne

Only one notable development of the school medical service at Eastbourne is recorded by Dr. W. G. Willoughby, and that is the increase of sessions for dental treatment from two to six half-days weekly. In other matters there has been an arrest; for example, the replacement of the old buildings at the open-air school has been postponed owing to financial stringency, though the main classroom and the rest shed badly need attention. This school, like the special mental defectives school, was a temporary building, adapted from army huts in 1920, an additional up-to-date classroom being added in 1929. It has proved a helpful adjunct to the school medical service, especially with children suffering from general debility and malnutrition; a few cases such as those of "observation mentality" or "post-rheumatic fever" would seem less likely to benefit from the special conditions provided in this school. The mental defectives' school continues to be useful, though not really fitted for its purpose. It is satisfactory to learn that for the first time since medical inspection was instituted no case of uncleanliness was found at the routine inspections; at the surprise inspections by the nurses 497 children were found to be unclean. No account is given of the progress of the health propaganda described in previous reports, nor is there any mention of the special class for stammerers that was formerly described by Dr. Coghill. The report of the organiser of physical training has not been printed. Dr. Willoughby's report for 1931 is thus less complete than was its predecessor.

Glasgow

The arrangement of this report does not take exactly the same form as those of English areas, and the figure for defects is probably not comparable. It is written by Dr. G. Arbuckle Brown with an introduction by Dr. A. S. M. Macgregor, and deals with the work done during the first complete year since the transfer of functions to the corporation under the Local Government (Scotland) Act of 1929. The effect of the coördination of the education health service with the other medical services of the corporation is held to be profound and beneficent. One result is that the medical supervision of the child from birth till the end of school life becomes the function of a unified service. Other results include:

> "The transfer of operations for tonsils and adenoids to the Western District Hospital; the more expeditous admission of necessitous cases for operations and medical treatment to the general hospitals; the surgical treatment of marked orthopædic deformities not formerly provided for, and the extension of all branches of orthopædic treatment and medical gymnastics; the supervision and control of infectious disease in schools by means of definite arrangements with the divisional medical officers of the health department; the housing of school treatment clinics in child welfare centres; the treatment in school clinics of minor ailments of children referred by the child welfare service; coördination with the clinic for the blind under the Blind Persons Act; coördination with the mental clinic for the supervision of mentally defective children; and in general, a closer, more intimate and effective linking up of the various medical services necessary for the welfare and supervision of child life in Glasgow."

The senior assistant medical officers of the educatio service, in coöperation with the sanitary inspector of each area, have begun a detailed and fruitfu survey of the sanitary conditions of the schools, an a still more interesting feature of the new system ha been the plan of inquiries embracing both the schoo and the home aspects of child life. One of thes inquiries affords exact statistics of the physique o the children at various ages during various periods divided into groups according to whether the familie occupy houses with one, two, three, or four rooms The arrangements for one sex and age—i.e., girl of 13—are set out in the following table:—

Age.	Year.	Heights.				Weights.			
		Number of apartments.				Number of apartment			
		1.	2.	3.	4.	1.	2.	3.	4.
13	1907	53·9	54·7	55·6	56·4	71·9	73·9	76·3	79·3
	1924	55·2	51·6	56·5	57·1	76·3	76·8	80·0	80·8
	1931	56·0	56·8	57·5	58·5	79·5	82·0	84·3	88·3

The degree of improvement which has taken plac in general is encouraging; it is of interest to not that the average heights and weights of the childre from one-apartment houses in 1931 are higher tha those of the children from the two- or three-apartmen houses in 1907. In the 5-year age-group the childre from the one-apartment houses in 1931 were talle than those from the houses of two apartments i 1907, but fell short in average weight. These observa tions are held to indicate that the improvement i height and weight is more marked after some year of school life.

Another inquiry shows the fall in prevalenc of rickets, the war years being omitted, whic in the three years ending 1914 was recorded a 9·0 per cent. of the school population, in th three years ending 1924 as 5·7 per cent., in the thre years ending 1929 as 4·2 per cent., and in 193 as only 3·0 per cent. Another set of statistics sho the percentages of school-children living in houses o one, two, three, four, or five or more rooms. Com parisons with previous years show that housin conditions in 1931 are much better than they wer 20 years ago, except in the single-roomed hous where they appear to be worse. Lastly, a record o the milk consumed daily per head has been compiled This works out to an average of 0·36 pints for childre in the poorest schools, 0·47 pints for those i "medium" schools, and 0·62 pints for those in th better-class schools. In 60 families no fresh mil was used.

OBITUARY

REMINGTON HOBBS, M.D. Brux., M.R.C.P. Lond.

Dr. Albert Remington Hobbs, who had been medical superintendent of St. Mary Abbot's Hospital, Kensington, for some 15 years, died on May 30th after a serious operation. He was at work less than a fortnight before his death.

ALBERT REMINGTON HOBBS.

Remington Hobbs was trained at St. Mary's Hospital, whence he qualified M.R.C.S., L.R.C.P. in 1901, becoming M.R.C.P. in 1930. He took the M.D. Brux. with honours in 1908. After qualifying he held appointments at St. Mary's Hospital as house surgeon, house physician, resident obstetric officer, casualty officer, and resident anæsthetist. He worked also for a time as assistant demonstrator of pathology and as ophthalmic house surgeon at St. Mary's, and as clinical assistant to St. Peter's Hospital and to the Paddington Green Children's Hospital and the Samaritain Free Hospital. Dr. Hobbs had thus gained exceptionally wide experience before his first administrative appointment as assistant medical superintendent to the Paddington Infirmary. He held this post until 1907 when he started general practice in Golders Green. On the outbreak of the war he left his practice at short notice to serve in the Army. He was, however, soon invalided out, and held the post of medical superintendent at Bethnal Green Infirmary before being appointed in the same capacity to St. Mary Abbot's Hospital, Kensington, where he became well known especially in connexion with the treatment of puerperal sepsis. He first became interested in the subject 13 years ago, and eventually worked out a line of treatment which proved extremely successful in his hands. This was based on his conviction that puerperal sepsis is, for the most part, an autogenous infection superadded to imperfect drainage. He showed that latent bacilluria is common in pregnant women, that puerperal sepsis can exist without pyrexia, that after-pains are abnormal and significant of sepsis, and finally, that with perfect drainage brought about by intra-uterine injections of glycerin many cases are cured. He believed that in many of the more serious streptococcal infections early uterine drainage would prevent the spread of infection and a general septicæmia. So enthusiastic was he in this special work that he started a clinic for teaching his methods, and during the last ten years medical men from almost every country in the world have attended his demonstrations. His methods were not at first generally accepted, but his enthusiasm remained undiminished and it was a source of great satisfaction to him in recent years to find a growing interest among gynæcologists in his work. Three days after his fatal illness began he was awarded the Triennial Gold Medal of the West London Medico-Chirurgical Society for distinguished work, and the news of this honour greatly comforted him during his last few days of life. In addition to his official appointment at St. Mary Abbot's Hospital, he was consulting gynæcologist to the Royal Borough of Kensington. This appointment was welcomed by the medical profession in the district, for he had their entire confidence.

A colleague writes: "Remington Hobbs was not only a medical man keenly interested in the specialty he had made his own, but also a splendid sportsman. He and his brother (E. C. Hobbs) were for some time the first wicket batsmen for St. Mary's Hospital, and Remington made a fine century against St. Thomas's when St. Mary's won the Hospital Cup in 1899. With his brother he put on 104 runs for the first wicket when playing for St. Mary's against Dr. W. G. Grace's London County Eleven in 1900. Afterwards he played for the Middlesex Second Eleven and for some years for Buckinghamshire, and he was playing in London club cricket and making good scores until two years ago. Hobbs was a lovable person and a delightful companion. He was so good natured, so kindly, that it was difficult to differ from him. His home life was particularly happy, and much sympathy will be felt for his widow and his two boys."

Dr. Leonard Colebrook writes: "It says much for his enthusiasm and industry that Remington Hobbs, while carrying all the cares of a large poor-law infirmary, was able to make a name for himself as the advocate of a particular form of treatment. Instillation of glycerin into the infected uterus had occasionally been tried in the past, but had not attracted special attention. Indeed, at the time (1920–23) when Hobbs became interested in the puerperal infections almost every remedy had become largely discredited. Inspection of the genital tract to determine what was the condition of the cervix and vaginal vault was seldom made, and if there was obstruction to the outflow of the discharge through the cervical canal, it was scarcely ever recognised. To Remington Hobbs, more than to *any other* man, is due the changed attitude with regard to this condition. He recognised that drainage, both of the uterine cavity and of the infected tissues, was a vitally important factor in recovery, and that the application of glycerin was likely to facilitate such drainage. Having satisfied himself that dramatic improvement in the patient's condition did frequently follow the instillation of glycerin he set himself to perfect the technique of the operation so that it could be carried out, if necessary, several times a day without undue pain or discomfort for the patient. It is not too much to say that he set up a new standard of skill (and of gentleness) in the examination and treatment of the patient with a postnatal infection. Not content with the improved results in the cases of established infection admitted to his hospital, he worked unceasingly by the same methods to control the mild pyrexias in his own maternity department—and also to bring the success of the 'glycerin treatment' to the notice of others.

"To many his single-minded enthusiasm and the orderly—almost oratorical—presentation of his thesis carried conviction. Others asked for statistical proof of the success of the method. Such proof could, however, scarcely be expected. The group of puerperal infections is too heterogeneous, and the tendency to spontaneous cure in the less severe cases is too high to admit of statistical treatment. Probably the careful study by H. J. Phillips, of Manchester (presented to the Section of Obstetrics of the Royal Society of Medicine in 1926), comes nearer than anything else to statistical proof of the value of the method. As so often in medicine, we have to proceed in the absence of complete proof, and the safest way is to be guided by such principles as appear to have a sound basis. To those who are familiar with the filthy condition of the infected uterine cavity post mortem (comparable only to the filthy wounds seen in the earlier days of the Great War), and are familiar also with the convincing experiments of Sir Almroth Wright on the importance of maintaining a flow of 'uncorrupted' lymph through infected tissues, there can be little doubt that the frequent instillation of a lymphagogue such as glycerin into the infected uterus must frequently be beneficial. While we may hesitate to go all the way with Hobbs in the interpretation of his results, most of those who have had experience of a number of cases treated by his method are well satisfied of its advantages. Personally, as one who has watched the march of events in connexion with puerperal fever over a number of years, I venture to assert that Hobbs's work has contributed more than anything else towards progress in the control of these puerperal infections."

ANDREW BOUTFLOWER, M.R.C.S. Eng.

Dr. Boutflower, who died at his home at Kersal on June 1st, was for many years senior surgeon of the Salford Royal Hospital. He was born at Salford in 1845, and was educated in Dublin and Manchester. On qualification as M.R.C.S. and L.S.A. in 1868 he became house surgeon at the Manchester Royal Infirmary. His father, John Boutflower, F.R.C.S., who had been surgeon to Salford Royal Hospital for 44 years, resigned in 1870, and the son took his place, remaining on the active staff from 1871 to 1911 when the institution was enlarged. He was also honorary surgeon to the Chetham Hospital, visiting surgeon to H.M. Prison, Strangeways, and medical visitor for lunatics for the county magistrates. He had a large practice in Salford and the neighbourhood. His chief outside interest centred in the Manchester Cathedral, of which he was at one time church warden. The name of Boutflower carries one a long way back in the medical history of Salford. John Boutflower lived from 1798 to 1889, and father and son between them served the Royal Hospital for 84 years.

CUTHBERT CHRISTY, M.B. Edin., F.R.G.S.

Dr. Cuthbert Christy, who died in the Belgian Congo on May 29th, was born at Chelmsford, educated at Oliver's Mount School, Scarborough, and went on to Edinburgh to study medicine, graduating in 1892. For three years he travelled in South and Central America, then joined the West African frontier force in Northern Nigeria, and later assisted Haffkine in his Plague Laboratory at Parel, Bombay. A short period as civil surgeon in lowland India was followed by extensive travel in the northern mountains, and in 1902 his rich experience and qualification led to his appointment as a member of the first Sleeping Sickness Commission in Uganda, and later of an expedition sent out to the same region by the Liverpool School of Tropical Medicine. On returning he lectured at this school for three years, followed by a further period of travel in East Africa and Uganda. During the war Dr. Christy became adviser for malaria in the East Africa expeditionary force with charge of the malaria hospital at Dar-es-Salaam. After the war he continued his expeditions in Central Africa, collecting specimens of rare animals and birds. Recently he had been serving on a Commission appointed by the League of Nations to inquire into the existence of slavery in Liberia. He was a great traveller, naturalist, and humanitarian.

MARCUS SINCLAIR PATERSON, M.D. Durh.,

LATE MEDICAL SUPERINTENDENT OF COLINDALE HOSPITAL.

We regret to announce the death on June 1st, in his 62nd year, of Dr. Marcus Paterson, who will long be remembered for his pioneer work on the institutional treatment of tuberculosis.

DR. MARCUS PATERSON.

[Photograph by Elliott & Fry

Marcus Sinclair Paterson was born in Scotland and on leaving school spent an apprenticeship of two years in the shipyards of Messrs. Inglis and Co. at Glasgow. Deciding then upon a medical career he entered as a student at St. Mary's Hospital and qualified as M.R.C.S., L.R.C.P. in 1894, and after further work at Newcastle Infirmary graduated M.B., B.S. Durh. in 1895. He then spent three years as a ship's doctor in the service of the P. and O., on leaving which he became house physician at the East London Hospital for Children. Here he worked in particular under the late Dr. Eustace Smith, to whose clinical judgment and sound methods he always attributed a great influence on his own life work. That work he may be said to have started when he was appointed resident medical officer at Brompton Hospital for Consumption. He threw himself into the conduct of the institution with zeal, and made a great impression upon the staff by the thoroughness of his methods, so much so that Sir James Kingston Fowler, with whom he came into close contact, said of him "if there were more Marcus Patersons there would be fewer cases of tuberculosis."

At Brompton he showed his powers of organisation to such effect that the authorities had no hesitation in appointing him as medical superintendent at the Frimley Sanatorium when that institution was opened. Their prompt choice was fully justified, for Paterson's gifts found full scope there. He became a prominent member of the small group who established the lines of sanatorium treatment of tuberculosis in this country. While the original inspiration of the methods for which he became so well known can be traced to the teaching of Otto Walther of Nordrach, Paterson's experience, acquired in the yards and drawing office of one of the largest Tyne-side shipbuilding firms, enabled him to view the problems of tuberculosis from the angle of the workmen. Like Walther devoid of deep scientific knowledge, he had a great fund of common sense and a capacity for seeing essentials. Walther relied upon graduated walking as best qualified to bring the convalescent tuberculous subject into the physical health necessary for return to work. Paterson, in association with Arthur Latham and Conyers Inman, substituted for walking a system of graduated exercises. He recognised that the working man would have a much better chance of obtaining and retaining his occupation if he could be discharged from a sanatorium with a proven capacity for performing his ordinary tasks, and he and his collaborators at Brompton were able to bring forcible arguments forward in proof that graduated labour was as serviceable as walking in the treatment of the convalescing subject. Paterson was fortunate to be linked in this work with Inman, who was an accomplished and enthusiastic bacteriologist, and who demonstrated by immunity reactions the beneficent effects of controlled auto-inoculation. In one form or another the principles thus laid down were adopted in all British sanatoriums which provided for the industrial classes. It required courage and a high conviction of the soundness of both theory and practice to induce patients with lung disease, who were taught to rest and to avoid any strain, to engage in physical labour, however light, and it is there that Paterson's personal qualities and past experience stood him in such good stead. He was loyally supported by the patients at Frimley who willingly coöperated in the methods—indeed Latham once testified that the difficulty was to restrain them in their desire to proceed quickly up the grades instituted. The actual pattern of labour which Paterson first laid down has since been modified, its seven grades having been reduced to four and their severity mitigated; but the workshops and industrial settlements of the present day are its lineal descendants. A description of the actual methods as originally laid down will be found in his monograph "Auto-inoculation in Pulmonary Tuberculosis" and briefly in the "System of Treatment" by Latham and English.

His experience in the engineering shops and on board ship had convinced him that to be out of work was worse than to be suffering from tuberculosis, and that to keep the quiescent case healthy on discharge from the sanatorium it was essential that he should obtain remunerative work, and, if possible, the work to which he was accustomed. The usual recommendation that a town worker should attempt to obtain employment on the land or as a seaman, because of the open-air environment, he contended to be entirely wrong, for the labour would not necessarily be lighter while inexperience would tend to make it harder. Hence with vague recommendations that the tuberculous subject should "go abroad" he had no patience, pointing out both how difficult it must be to secure with certainty any work abroad, and how much easier it is to starve anywhere else than in England.

The excellence of Paterson's work was recognised at the International Congress of Tuberculosis at Washington in 1908 where the first prize for an exhibit of sanatorium treatment was awarded to the Frimley Sanatorium, and the first prize for hospital treatment of tuberculosis to the Brompton Hospital, the accompanying essays being the work of Paterson, of Latham, and of Inman. For two of the essays Paterson was awarded first prizes. From Frimley, Paterson went in 1916 as medical director to the King Edward VII. Welsh National Memorial Hospital, and after three years' busy work there was appointed medical superintendent of the M.A.B. tuberculosis hospital at Colindale, where he remained for the residue of his professional life, and where he continued to display the same practical interest in the individual patients, estimating their chances by their capacities and attainments, and sparing no effort to help those who were prepared to help themselves.

Throughout this sequence of important institutional appointments Marcus Paterson was as popular with his colleagues as with the patients. He was a man of a robust and engaging personality, tenacious of any purpose he had in view and untiring in carrying out his ideas, while he had a ready wit and facile repartee. His mordant criticism, where he thought that criticism was due, was well shown in a book, published in 1920, and entitled "The Shibboleths of Tuberculosis," in which, one after another, much of the routine teaching of an older generation was dissected and consigned to oblivion. He stamped as shibboleths such things as the belief that cod-liver oil was essential in the treatment of tuberculosis, that the victim of hæmoptysis must be confined to cold food and drink, that tuberculous empyemas should be opened, and, especially, that change of climate is good for tuberculosis. All the strictures in this valuable and entertaining book were not acceptable, and of some it may be said that they did not deserve to be accepted, but as a whole the work was as sound in teaching as entertaining in style. In later years a motor accident and undulant fever interfered with his activities, and he retired at an age when many men are able to proceed in the fulfilment of earlier promise. Paterson's life-work ceased prematurely, but he had done enough to secure a place for himself in the ranks of his important specialty.

In private life Marcus Paterson was a deservedly popular man; his blunt exterior covered a sympathetic disposition, and he gained the high regard of those with whom he worked and of those with whom he spent his leisure. At the Savage Club, where he was honorary treasurer, he was a highly popular member, while his hobby as a dog-breeder gained for him many prizes and many sporting friends.

PAUL MORGAN CHAPMAN, M.D. Lond., F.R.C.P.

WE regret to announce the death of Dr. Paul Chapman which occurred suddenly at Chatham, on Tuesday, May 31st, in his eighty-first year.

Paul Morgan Chapman was educated at Shrewsbury and University College Hospital. He took the English double diplomas in 1875 and two years later graduated as M.B. Lond, proceeding to the M.D. three years later. For a brief time he was in private practice, unattached to any hospital, and more devoted to the study of Elizabethan literature and classical music than to that of clinical medicine, but he made a reputation as a coach and especially women students sought his assistance. An introduction to Burdon-Sanderson, however, gave him at this time a taste for experimental physiology, and a series of observations on the heart, which accorded with that great physiologist's conclusions, led to an immediate and enthusiastic interest in cardiac disease; then he was invited by Bristowe, whose text-book of medicine which 50 years ago was read by every student had recently appeared, to revise the article on heart disease. In 1894 he delivered the Goulstonian lectures on the Physics of the Circulation. These formed an accurate and scholarly résumé of the knowledge of the day, and were prefaced by an expression of gratitude to Burdon-Sanderson for encouragement received in the experimental work and its graphic representations. These lectures closed with an acknowledgment to the Board of the Hereford General Infirmary for their enlightened assistance, and in those words we have a clue to the reason why Chapman's striking entrance into the field of clinical research was not followed by commensurate results.

The following has been supplied to us by an intimate friend :—

"At University College, over 50 years ago, a friendship began between Paul Chapman and myself which remained unbroken to the last—indeed, he had proposed visiting me on June 1st, just 48 hours before the fatal attack. That he did not take scientific honours at the College was due to no lack of ability, nor to wasted opportunities in the ordinary way, but to his love for Elizabethan literature and music. In the pursuit of the former much of his time was spent in the British Museum over old plays which might have been given to his medical studies, but it was not in a nature of his kind to keep his nose to the grindstone. His tastes from boyhood had taken him to the poets and as a child, it seemed, he would take a volume of Shelley to bed, and Shelley remained to the end his favourite poet, from whom he could repeat long passages even in his last years, as he could with Shakespeare's sonnets and plays. Soon after taking his degree he repeated, at the request of Burdon-Sanderson, a series of confirmatory observations on the heart, which gave him a taste for experimental physiology, especially in its application to cardiac disease. Partly as an outcome of this work he suggested to Bristowe that the article on heart disease in the recent text-book might be improved, and the criticism being accepted by the author Chapman was asked to write a substitute, which he accordingly did. It looked at this time as if a career were opening to him in London and, had he been able to pursue his opportunities, he would, I have little doubt, have taken a position of prominence, especially in cardiac maladies. Unfortunately all such hopes had to be abandoned for a recurring conjunctivitis, owing largely to the dust in London, led Mr. Tweedy (Sir John) to advise his seeking some place in the country. This, for one who was leaning towards a consulting practice and who enjoyed the contact with others like situated was a serious blow, but he recognised the wisdom of the advice. The senior physician to the Herefordshire General Infirmary had just died and Chapman applied for the hospital appointment, obtained it and started in Hereford as a consultant in 1886, and practised in the city until his retirement in 1919. During the war—his three sons were serving—he was physician to the V.A.D. Hospital at Hereford and consulting physician to another institution and for these services was awarded the M.B.E.

"Throughout his career he kept himself informed of the literature of cardiology in this country and abroad, and his position was honourably recognised by his appointment as Goulstonian lecturer at the Royal College of Physicians of London, on the Physics of the Circulation. The lectures were models of clearness, for Chapman possessed notable literary attainments. He was at one time a frequent contributor to the *Nineteenth Century*, and until recently he contributed articles to the *Yorkshire Post* in style much like those of the third 'leader' in the *Times*, in which he displayed a remarkable knowledge of ancient and modern literature. The titles of some of these are suggestive—e.g., 'On Staying at Home,' 'The Grace of the Crinoline.' 'Heroic Metre,' and 'Songs of Spring'—the last written just before his sudden death.

"After his retirement he lived with his wife in part of the Old Rectory at Cascob, on the borders of Radnor Forest, where his wife, the daughter of a former rector, was born. Here he wrote a 'Foot Guide to Radnor Forest,' which was notable, not only for its practical information, but for its wealth of historical allusions and its poetic description of the beauties of the forest. He was a keen fly fisherman and up till recently would spend a week on one of the Welsh rivers, usually with his son, where his skill in guiding a boat through the upper Wye with its many 'streams' and his powers as an oarsman were notable. He was a strong swimmer and, leaving the boat, with his companion (the writer) would thus propel it through the smooth water in Symonds Yat. He was also above the average as an amateur actor, and in support of his hospital compiled, organised, and directed plays, which were performed on a lawn with suitable background, taking himself a leading part. His rendering of Malvolio was an excellent performance, and in order to perfect his part he took advice and help from a prominent London actor. He played the 'cello in a musical society, which he established in Hereford."

The loss of his eldest son in the war was a severe blow to Chapman. He is survived by two sons, both of whom are in the Royal Navy.

ROYAL FREE HOSPITAL

ON June 8th the Queen visited the hospital to open the Queen Mary Building (Albert Levy Wing) and to lay the foundation-stone of the extension to the nurses' home. The extension was much needed for the better accommodation of the maternity, antenatal and postnatal departments, and for the orthopædic and physical medicine units. It was also necessary to provide new kitchens and to install a new heating system. The total cost of the new building and its equipment was estimated at some £250,000. After subscriptions amounting to about £60,000 had been secured, Sir Albert Levy, the hospital treasurer, contributed £55,500 on the understanding that a substantial section of the building should be constructed and brought into use without delay.

The entrance to the Queen Mary Building from the body of the hospital is in a small inner court whence a flight of wide stone stairs leads to a pillared hall. Through this hall may be approached the administrative quarters of the maternity unit, which includes an antenatal and postnatal unit and occupies half of the ground floor of the wing. The various rooms are built to open out of one large central waiting hall, which is fitted with a coffee bar. Mothers can easily be called from this hall to the registration counter, the case-taking room, the separate dressing cubicles, and cloakrooms, and directly from these to the six consulting and examination rooms. The unit has a separate dispensary and a social service room. For students a library and a lecture room have been provided.

The other half of the ground floor of the wing, with the corresponding lower ground floor, houses the department of physical medicine and orthopædics. Curtained dressing cubicles adjoin the treatment rooms. In the orthopædic room is a couch for manipulative surgery and minor operations. Curative exercises are carried out under the direction of the orthopædic surgeon in a fully equipped gymnasium.

The heating system adopted throughout is that of steam-heated panels built into the walls. In the wide central court round which the wing is built, a hard tennis-court has been constructed for the use of the nurses and medical staff.

Nurses' Home Extension.—The first block of the Nurses' Home was erected at a cost of £60,000. It is now necessary to complete the Home at a further cost of £60,000 of which, according to the annual report of the hospital for 1931, only £22,500 is in hand ; a further £30,000 is to be taken from investments, and a balance of £7500 has still to be obtained.

The Queen was received by Lord Riddell, the President of the hospital, Sir Albert Levy, the hon. treasurer, and Miss G. M. Bulman, the matron.

CROYDON GENERAL HOSPITAL.—It is proposed *to extend the accommodation* of this hospital from 130 to 190 beds, including 17 for paying patients. The cost will be £37,000, of which £17,000 is in hand.

MEDICAL NEWS

University of London

At recent examinations the following candidates were successful:—

Honours.—T. A. L. Davies (*c*, *d*, *c*, University Medal), St. Thomas's Hosp.; K. H. C. Hester (*a*, *c*), London Hosp.; P. M. G. Russell (*c*), Univ. Coll. Hosp.; E. F. Scowen (*d*), St. Bart.'s Hosp.; Eileen M. Whapham (*d*), Roy. Free Hosp.; and S. L. Wright (*a*), Univ. Coll. Hosp.

(*a*) Distinguished in Medicine. (*c*) Distinguished in Forensic Medicine. (*d*) Distinguished in Surgery. (*c*) Distinguished in Obstetrics and Gynæcology.

Pass.—John Apley, Univ. Coll. Hosp.; H. B. Barker, St. Mary's Hosp.; W. S. Baxter, St. Bart.'s Hosp.; C. R. Birnie, King's Coll. Hosp.; J. B. Blaikley, Guy's Hosp.; A. E. Bowling and Winifred M. Burbury, Univ. of Leeds; Albert Burkhardt, Univ. Coll. Hosp.; Jack Carlton, Guy's Hosp.; R. C. Cohen, Univ. Coll. Hosp.; Margaret J. Cooper and Iris M. Cullum, Roy. Free Hosp.; James Dawson, Univ. Coll. Hosp.; Mary T. Day, Charing Cross Hosp.; Gwyneth N. Ellis, Roy. Free Hosp.; A. C. Frazer, St. Mary's Hosp.; Barton Gilbert, St. Thomas's Hosp.; G. P. Gladstone, London Hosp.; F. J. S. Gowar, Middlesex Hosp.; Hilary S. M. Hadaway and Kathleen M. Hart, Roy. Free Hosp.; D. K. Jardine, St. Bart.'s Hosp.; I. G. Jones, Univ. Coll. Hosp.; K. D. Keele, St. Bart.'s Hosp.; Alexander Kennedy, St. Thomas's Hosp.; Stephen Knight, Univ. Coll. Hosp.; Robert Knox, St. Bart's Hosp.; Samuel Leff, and H. G. McComas, Guy's Hosp.; N. F. Maclagan, Middlesex Hosp.; F. M. Mallinson, Univ. Coll. Hosp.; Esther M. Martin, Roy. Free Hosp.; L. G. Norman, Univ. Coll. Hosp.; H. J. C. Page, St. Mary's Hosp.; D. D. Payne, St. Thomas's Hosp.; Martin Phillips, London Hosp.; C. R. D. Porter, Middlesex Hosp.; S. R. C. Price, King's Coll. Hosp.; R. D. Reid and A. C. Riley, St. Bart.'s Hosp.; L. K. Robson, Guy's Hosp.; H. W. Salmon, Middlesex Hosp.; A. G. Sanders, St. Thomas's Hosp.; R. W. Scarff, Middlesex Hosp.; S. A. Scorer and A. G. Signy, Guy's Hosp.; D. A. Smith, St. Bart.'s Hosp.; G. L. Talwar, St. Thomas's Hosp.; Margherita N. Walden, Roy. Free Hosp.; Doris E. C. Walker, Univ. Coll. Hosp.; E. M. Ward, St. Bart.'s Hosp.; S. J. Wheeler, Guy's Hosp.; Shirley E. Whitaker, Univ. Coll. Hosp; and A. L. Wingfield, St. Thomas's Hosp.

The following students have passed in one of the two groups of subjects:—

Group I.—Hamish Allan, Middlesex Hosp.; Arthur Barber, St. Bart.'s Hosp.; G. N. Barker, St. Thomas's Hosp.; Mavis W. M. Beddall, Univ. Coll. Hosp.; W. H. Bradbeer, Guy's Hosp.; Joyce M. G. Clogg, Roy. Free Hosp.; P. A. Cooper, Univ. Coll. Hosp.; Kitty Fraser, Roy. Free Hosp.; R. G. Gilbert, St. Bart.'s Hosp.; George Gilchrist, Guy's Hosp.; A. M. Gill, Middlesex Hosp.; Reginald Glanvill, Guy's Hosp.; Lucy W. Grace, Roy. Free Hosp.; M. D. C. Hosford, St. Bart.'s Hosp.; W. P. Hedgcock, St. Thomas's Hosp.; Constance M. Hoare, King's Coll. Hosp.; Agnes V. Kelynack, Roy. Free Hosp.; L. W. Lauste, St. Thomas's Hosp.; J. T. R. Lewis, Middlesex Hosp.; Mary A. McKean, Roy. Free Hosp.; T. H. Parkman, Charing Cross Hosp.; Norah W. K. Petter and Leah Reder, Roy. Free Hosp.; J. F. Rivers-Moore, London Hosp.; Hetty C. Tester, Roy. Free Hosp.; and A. J. White, Middlesex Hosp.

Group II.—R. E. Angel, St. Bart.'s Hosp.; H. G. E. Arthure, Charing Cross Hosp.; F. R. Bettley, Univ. Coll. Hosp.; G. N. Carrell, Guy's Hosp.; G. T. W. Cashell, King's Coll. Hosp.; W. C. Cresdee, St. George's Hosp.; G. E. Dunkerley, Univ. Coll. Hosp.; A. C. Gladstone, St. Thomas's Hosp.; R. D. Green, London Hosp.; E. S. Harverson, Univ. Coll. Hosp.; M. S. Holzman, London Hosp.; J. S. MacVine, and I. W. Matheson, St. Bart.'s Hosp.; C. P. Seeley, St. Mary's Hosp.; S. F. Smith, St. Thomas's Hosp.; K. S. Southam, Guy's Hosp.; J. G. Stewart, Westminster Hosp.; J. L. Woodhouse, Guy's Hosp.; and Joshua Zeitlin, London Hosp.

Slaughter-house Methods and Equipment

The British Science Guild has appointed a committee of technical experts on Slaughter-house Methods and Equipment. The chairman is Sir Arnold Wilson, who was chairman of the Industrial Health Research Board in 1920; the vice-chairman is Captain C. W. Hume, hon. secretary of the Guild; and the hon. secretary is Mr. John McMath. The other members of the committee include representatives of the Institution of Mechanical Engineers (Mr. John Fearn), the Society of Medical Officers of Health (Dr. Charles Porter), the Model Abattoir Society (Sir James Douglas and Mr. R. Stephen Ayling), the Royal College of Veterinary Surgeons (Prof. F. T. G. Hobday and Lieut.-Colonel T. Dunlop Young), the Royal Sanitary Institute (Mr. J. R. Hayhurst), and the Royal Society for the Prevention of Cruelty to Animals (Lieut.-Colonel T. C. R. Moore, M.P., and Mr. R. O. P. Paddison). The Medical Research Council has also been invited to recommend a member. The terms of reference of the committee are as follows:—

> To verify and tabulate information relating to methods of, and equipment for, the slaughtering of animals for food, with especial reference to sanitary, dietetic, and human requirements; to investigate new methods and equipment; to convey information on the subject to local authorities and other bodies and persons.

University of Dublin

Trinity College.—Sir Gowland Hopkins, P.R.S., professor of biochemistry in the University of Cambridge, will deliver the John Mallet Purser lecture on Tuesday, June 14th, at 5 P.M., in the department of physiology. His subject is Some Aspects of Modern Biochemistry.

Indian Medical Service Dinner

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Wednesday, June 15th, at 7.15 P.M. Major-General J. W. D. Megaw will preside, and the guest of honour will be Sir Samuel Hoare, Secretary of State for India. Tickets and all particulars may be had from the joint hon. secretary, Sir Thomas Carey Evans, Hammersmith Hospital, Ducane-road, London, W. 11.

Post-graduate Course on Birth Control

A lecture and a clinical demonstration on the theory and practice of contraception will be held by Dr. Gladys Cox at the North Kensington Women's Welfare Centre at 6 P.M. on June 23rd and 30th respectively. A similar short course will be held on July 14th and 21st. Further particulars can be obtained from the honorary secretary of the clinic, 12, Telford-road, Ladbroke-grove, London, W.10.

St. John's Hospital Dermatological Society

Sir Thomas Lewis will deliver the annual oration of this society at a meeting to be held at the hospital, 49, Leicester-square. London, W.C., at 5.30 P.M. on Wednesday, June 22nd. His subject is Recent Observations on the Causation of Raynaud's Disease.—The annual dinner will be held at 7 for 7.15 P.M. on the same day at the Criterion Restaurant, Piccadilly-circus.

Société Française de Phoniatrie

On May 9th this society was formed in Paris for the study of questions relating to the physiology and pathology of the voice and speech. Prof. Moure is the president, Dr. Hautant and Prof. Lemaitre vice-presidents, and Dr. Tarneaud secretary-general. Dr. Tarneaud's address is 27, Avenue de la Grande-Armée, Paris, XVIe.

Biochemical Society

A meeting of this society will be held at the agricultural research station of Imperial Chemical Industries, Jealott's Hill, Bracknell, Berks., at 3 P.M., on Saturday, June 11th.

The Parkes Memorial Prize

The prize of 75 guineas in money and the gold medal of the Parkes Memorial Prize for 1931 has been awarded to Captain D. C. Ettles, R.A.M.C.

Merseyside Hospitals Council

The annual report of this council, which has now completed its fifth year of work, states that the total income of the 22 associated hospitals in 1927 was £227,000. Their total income for 1930 (the last year for which complete figures are available) was £269,500, an increase of £42,500. The task the council set itself to achieve in 1927 was to extinguish the annual deficit of the associated hospitals, which amounted to £31,500. The ordinary expenditure has, however, increased by £35,000 per annum; consequently the deficit, instead of being more than extinguished, had, by the end of 1930, been reduced only by £7000. It is pointed out that capital expenditure on extensions and improvements during the three years, 1928–30, amounted to £222,000, and it is added: "Much of this expenditure was no doubt essential for medical efficiency, but whether by closer coördination the efficiency of hospital service as a whole might not have been preserved with less capital expenditure is a question deserving close attention." Notwithstanding that at the end of 1931 the contributory scheme was collecting from over 275,000 persons, the decrease in patients' payments between 1927 and 1930 was only £3000. The ambulance work of the council has greatly increased, and last year 8381 patients were taken to and from the local hospitals at the request of the medical authorities.

Appointments

IRVINE, LILIAN, M.B., B.Ch., B.A.O., D.P.H. Belf., has been appointed Assistant Medical Superintendent at the Liverpool Sanatorium.

Certifying Surgeons under the Factory and Workshop Acts: DUNLOP, J. L., M.B., Ch.B. R.U.I. (Hornsea, Yorks); JENNER, C. W., L.M.S.S.A. (Haslemere, Surrey); and MCKEAN, T. S., M.B., Ch.B. Glasg. (Sutton-in-Ashfield, Nottingham).

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

The Town Planning Bill

IN the House of Commons on June 7th the Town and Country Planning Bill was recommitted. On Clause 6 (Preparation or adoption of schemes), Mr. GREENWOOD moved the omission of Subsection 2, which states that a resolution authorising the preparation of a scheme shall not take effect unless and until it is approved by the Minister.

Lieut.-Colonel FREMANTLE supported the omission of the subsection. He said that everybody of experience in town planning, whether voluntary associations or local authorities, supported the Bill as it was originally introduced and regretted that the subsection now proposed to be left out should have been introduced at the instance of the Property Owners' Association. The Association of Municipal Corporations were opposed to the subsection because it curtailed their power to deal with gradual change that might take place in the use of land and the character of buildings within the area of the scheme calculated to prejudice existing property or its amenities or the redevelopment of the land. Those who looked on town planning as a science in local government should be given a free hand because, unless they were untrammelled in covering the whole ground, the scheme was found to fall short of requirements.

The amendment was rejected by 305 votes to 50, and the Bill was read the third time.

Epsom College Bill

In the House of Lords on June 7th the Epsom College Scheme Confirmation Bill was read the third time and passed.

The Public Health (Cleansing of Shell-fish) Bill was read the third time and passed.

HOUSE OF COMMONS

THURSDAY, JUNE 2ND.

Royal Commission on Licensing

Mr. RHYS DAVIES asked the Home Secretary whether any legislation was to be introduced this session in connexion with the report of the Royal Commission on Licensing Laws (England and Wales).—Sir HERBERT SAMUEL replied: As the hon. Member will no doubt have anticipated, the answer is in the negative.

Factory Legislation

Major NATHAN asked the Home Secretary whether he proposed to introduce during the present session a Bill for the consolidation and amendment of the laws relating to factories.—Sir HERBERT SAMUEL replied: I regret there is no possibility of such legislation this session.

Petrol Fumes from Omnibuses

Mr. DAGGAR asked the Home Secretary what steps were taken by his department at present for testing public omnibuses in respect of petrol emanations (fumes and exhaust); if he was satisfied as to their effectiveness; and if he was aware that a number of conductors and drivers of such vehicles were reporting sick, with headache and gastritis, owing to this cause.—Sir HERBERT SAMUEL replied: Every omnibus is given a running test before being licensed, special care being taken to see that no excessive or obnoxious fumes are emitted; and if any vehicle, after being licensed, is seen to be offending in this respect, the licence is suspended and it is removed from service until the defect has been remedied. I have no reason to doubt the general effectiveness of these arrangements; and so far as I am aware only two cases have occurred during the present year in which it is claimed that sickness has resulted from the cause suggested.

Supply of Milk to School-children

Captain HEILGERS asked the President of the Board of Education whether, in view of the increased use of milk in elementary schools in the last year, he would take steps to encourage the further consumption of milk in all schools while at the same time insisting that wherever possible only Certified or Grade A milk should be used.—Sir DONALD MACLEAN replied: I am anxious to see a further extension of the arrangements for the supply of milk to children in public elementary schools, and I a[illegible] National Milk Publicity Council to [illegible] arrangements for the provision of milk by local education authorities, the Board call the attention of the authorities to the importance of their satisfying themselves as to the purity and quality of the milk, and they recommend the use of pasteurised or tuberculin-tested milk.

Cancer Research

Dr. MORRIS-JONES asked the Minister of Health how much of the grant provided by Parliament annually towards the expenditure of the Medical Research Council was allocated for cancer research; how many cancer research workers there were receiving financial assistance; on what basis the individual research workers were selected, and what was the amount of grant received by each, respectively.—Sir E. HILTON YOUNG replied: No special allocation of any part of the inclusive grant in aid received by the Medical Research Council from the Exchequer is made to cancer research as such. I am advised that in our present state of knowledge it is in fact neither possible nor desirable to decide the present or future relevance of particular new lines of inquiry to the special problem of cancer. To work expressly directed to cancer the Council assign at present about £6000 a year, exclusive of expenditure upon radiology and radiotherapy. The work supported by the Council is described in the annual reports which are presented to Parliament, but it is not the practice of the Council to give details of the amount of the grants paid to individual research workers.

Danger of Swamp Fever in Doncaster Area

Mr. THOMAS WILLIAMS asked the Minister of Health what steps the sanitary and health authorities were taking in the Doncaster area to avoid the danger of swamp fever spreading when the floods subsided; and whether his department would undertake to bear any portion of the financial responsibility involved in these measures.—Sir E. HILTON YOUNG replied: I understand from the reports of my inspectors, who, since the floods began, have been and still are upon the spot for the assistance (inter alia) of the local authorities, that the local medical officers of health have been actively engaged in inquiries into the possibility of danger to health, with special reference to the question of pollution of the water-supplies and such dangers as those referred to in the question. The resources of my department are immediately available for their assistance, advice, and support as may be required; but there are no funds at my disposal for the purpose suggested in the last part of the question.

Vaccination in the Army

Mr. NEIL MACLEAN asked the Financial Secretary to the War Office for what reasons an Army order or instruction had been issued to Army medical officers instructing them to discontinue the use of boracic lint and of vaccination pads, and notifying them that when the present stocks were exhausted no further issue of vaccination pads, &c., would be made; whether this order meant vaccination in the Army was to cease; and, if not, whether he would state the purpose of this order.—Mr. DUFF COOPER replied: The decision not to issue further supplies of boracic lint and vaccination pads was made in the interests of economy. Boracic powder and plain lint will be issued instead. The answer to the second part of the question is in the negative.

MONDAY, JUNE 6TH.

Naval Ratings and Invaliding

Sir BERTRAM FALLE asked the First Lord of the Admiralty the number of naval ratings invalided during the year 1931, and the number during this period whose invaliding disability was considered to be attributable to service; and the number of naval ratings invalided during this period with tuberculosis, and the number awarded disability pensions for this disability.—Lord STANLEY (Parliamentary Secretary to the Admiralty) replied: The number of Naval ratings (including Royal Marines) invalided during the year 1931 was 888, and the number whose disability was considered to be attributable to the Service was 193. The number invalided during that period with pulmonary tuberculosis was 156, and in 117 of these cases pensions were granted on the attributable scale.

Sir BERTRAM FALLE asked the First Lord of the Admiralty the number of boy ratings of all branches of the Roya.

Navy and Royal Marines who were invalided during the year 1931, and the number in the same period who were invalided with tuberculosis, heart complaints, and kidney trouble.—Lord STANLEY replied: The number of boy ratings of all branches of the Royal Navy and Royal Marines who were invalided during the year 1931 was 54; the numbers in the same period who were invalided with pulmonary tuberculosis, heart complaints, and kidney trouble were 3, 12, and 2 respectively.

TUESDAY, JUNE 7TH.

School Dental Service

Captain HEILGERS asked the President of the Board of Education the average number of children for whom a dental surgeon was provided by local authorities; and whether he was satisfied that the number of dental surgeons was sufficient.—Sir D. MACLEAN replied: The number of dentists employed by local education authorities under the school medical service is equivalent to one dentist for approximately 9000 children in average attendance. While considerable progress has taken place in recent years, I am fully aware that in many areas there is not a complete dental service.

Miners' Welfare Fund

Sir WILLIAM JENKINS asked the Secretary for Mines what progress was being made with the committee of inquiry into the miners' welfare fund; and when the report was likely to be published.—Mr. FOOT replied: I am informed that the committee expect to complete their taking of evidence this month, and hope to present their report in the early autumn.

Alleged Overcrowding in Paddington

Mr. GOLDIE asked the hon. Member for Central Leeds (Mr. Denman), as representing the Ecclesiastical Commissioners, whether he was aware of the defective condition of, and the overcrowding existing in, the estates controlled by the Commissioners in the borough of Paddington: what steps it was proposed to take to remedy the conditions; and, in particular, what sum it was proposed to expend during the current financial year in alterations and improvements.—Mr. DENMAN replied: The allegation in this question appears to be that houses in the borough of Paddington under the control of the Ecclesiastical Commissioners are suffering from overcrowding or defective conditions. Far from being aware of this. I invite the hon. Member either to substantiate the allegation or publicly to withdraw it.

Coal-dust and Anthracosis

Sir WILLIAM JENKINS asked the Lord President of the Council whether the Medical Research Council was still inquiring into the effect of coal-dust upon underground workers who were suffering from anthracosis: and, if so, when the report would be published.—Mr. BALDWIN (Lord President of the Council) replied: The matter continues to receive the attention of the Industrial Pulmonary Diseases Committee of the Medical Research Council, but I am advised that serious difficulties are still being met in finding trustworthy methods of investigation. There is at present no question of a report.

Imports of Bromine

Sir ALFRED KNOX asked the President of the Board of Trade what amount of bromine had been imported into, and exported from, this country since May, 1931: and what proportion, if any, had been consigned to Germany or Russia.—Mr. RUNCIMAN replied: During the 12 months ended April 30th. 1932. the total imports of bromine and bromides into the United Kingdom amounted to 12.410 cwts., and the exports to 1093 cwts. (including re-exports 664 cwts.). No exports of bromine or bromides were registered during this period as consigned to the Soviet Union, and the only consignments to Germany consisted of 5 cwts. re-exported.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 28th, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 68 (last week 54); scarlet fever, 1346: diphtheria, 681; enteric fever, 28; acute pneumonia (primary or influenzal), 832; puerperal fever, 35; puerperal pyrexia, 111; cerebro-spinal fever, 69; acute poliomyelitis, 4; acute polio-encephalitis, 1: encephalitis lethargica, 13; dysentery, 14; ophthalmia neonatorum, 109. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on May 31st–June 1st was as follows:—Small-pox 84 under treatment, 2 under observation (last week 89 and 5 respectively); scarlet fever, 1554; diphtheria, 1309; enteric fever, 9; measles, 2314; [illegible] puerperal fever, 15 (plus 6 babies): [illegible] 227; poliomyelitis, 3; "other [illegible] Margaret's Hospital there were 16 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was one death from small-pox, 2 (0) from enteric fever. 74 (26) from measles, 7 (2) from scarlet fever, 34 (3) from whooping-cough, 22 (6) from diphtheria, 40 (13) from diarrhœa and enteritis under two years, and 29 (4) from influenza. The figures in parentheses are those for London itself.

Small-pox was mentioned as the cause of death in a case provisionally assigned to Bermondsey (Met. Borough). The fatal cases of enteric fever outside London occurred at Stockport and Birmingham. Liverpool reported 13 deaths from measles, Burton-on-Trent 4, and Bootle 3. Four fatal cases of whooping-cough occurred at Liverpool and 4 at Manchester. Diphtheria accounted for 5 deaths at Liverpool, 3 at Leeds.

The number of stillbirths notified during the week was 270 (corresponding to a rate of 36 per 1000 total births), including 51 in London.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY, June 16th.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.). Mr. H. Corsi: Rare Type of von Recklinghausen's Disease.

FRIDAY.—8.15 P.M., OBSTETRICS AND GYNÆCOLOGY. Mr. L. Carnac Rivett: Modern Methods for Alleviating Pain in Childbirth. (A discussion will follow.) Dame Louise McIlroy: Indications for Cæsarean Section.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, June 14th.—9 P.M. (at the Great Western Royal Hotel, Paddington, W.), Annual Meeting. Dr. G. de Swietochowski: A Doctor's Mandate. (Presidential Address.)

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Manson House, Portland-place, W.

THURSDAY, June 16th.—8.15 P.M., Discussion on Synthetic Anti-Malarial Preparations and Quinine, to be opened by Col. S. P. James, and continued by Prof. W. Schülemann of Elberfeld, Prof. N. H. Swellengrebel of Amsterdam, Dr. C. A. Henry, Sir Henry Dale, and Dr. Keilin.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

MONDAY, June 13th.—2.15 P.M., Mr. Frederick Roques: Prolapse. 3.15 P.M., Mr. W. B. Gabriel: Surgical Ward Cases.

TUESDAY.—2.15 P.M., Mr. McNeill Love: Some Common Diseases of Bones. 3.15 P.M., Dr. Bruce Williamson: Rational Use of Digitalis.

WEDNESDAY.—2.15 P.M., Mr. A. M. Zamora: Atypical Mastoid Infections. 3.15 P.M., Dr. B. Buckley Sharp: Modern Methods of Treatment of Neurosyphilis in Practice.

THURSDAY.—2.15 P.M., Dr. A. Lisle Punch: Cardiac Arrhythmias in General Practice. 3.15 P.M., Mr. L. E. Barrington-Ward: Demonstration of Surgical Cases.

FRIDAY.—2.15 P.M., Dr. W. R. Reynell: The Epilepsies and Allied Morbid Conditions. 3.15 P.M., Mr. Hamilton Bailey: Lecture Demonstration.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, June 13th.—10 A.M., Gynæcological Wards, Skin Dept. 2 P.M., Surgical Wards, Gynæcological and Eye Out-patients.

TUESDAY.—10 A.M., Medical and Surgical Demonstrations. 2 P.M., Throat Out-patients. 4.15 P.M. (Lecture). Mr. Steadman: Pyorrhœa.

WEDNESDAY.—10 A.M., Medical Wards, Children's Out-patients. 2 P.M., Eye Out-patients.

THURSDAY.—10 A.M., Neurological Out-patients, Fracture Demonstration. 2 P.M., Eye and Genito-Urinary Out-patients.

FRIDAY.—10 A.M., Medical Wards, Skin Dept. 2 P.M., Throat Out-patients. 4.15 P.M. (Demonstration). Dr. Archer: Biochemical.

SATURDAY.—10 A.M., Children's Out-patients, Medical Wards, Operations, Medical and Surgical Out-patients daily at 2 P.M. 4.15 P.M., Lectures open to all Medical Practitioners without fee.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, June 15th.—Mr. R. H. J. Swan: Genito-Urinary Tuberculosis.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, June 13th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Cerebral Aneurysms.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Adie: Disseminated Sclerosis.

WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Vertigo.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Carmichael: Syringomyelia.

ST. MARK'S HOSPITAL, City-road, E.C.

THURSDAY, June 16th.—4.30 P.M., Mr. J. P. Lockhart-Mummery: Rectal Abscess.

ST. PETER'S HOSPITAL, Henrietta-street, W.C.

WEDNESDAY, June 15th.—3 P.M., Mr. Clifford Morson: Congenital Abnormalities of the Kidneys and their Treatment.

NATIONAL CENTRE AND POST-GRADUATE SCHOOL OF RADIOTHERAPY, Riding House-street, W.

WEDNESDAY, June 15th.—4.30 P.M., Mr. Douglas Harmer: Nasal Sinus.

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Asst. M.O. for Radium Department.

Altrincham General Hospital.—Sen. and Jun. H.S. At rate of £150 and

Bath, Royal -Fourth Hon. Surgeon.

Bedford Cou S. At rate of £140.

Belfast, Quee Tutor. £200.

Birkenhead C t. M.O. £350

Birmingham. Cadbury Bros., Ltd, Bournville.

Birmingham Queen's Hospital.—Res. Surg. O. and Res. Surg. Reg. £150 and £100 respectively.

Blackburn Royal Infirmary.—Fourth H.S. £150.

Brighton County Borough, Public Assistance Committee, Poor-law Institution.—Res. M.O. £850 and Sen. Res. Asst. M.O. £400.

Bristol, Ham Green Hospital and Sanatorium.—Jun. Asst. M.O. At rate of £250.

Burnley, Victoria Hospital.—H.P. At rate of £150.

Burton-on-Trent, Bretby Hall Orthopædic Hospital.—Locum. At rate of £350.

Bury Infirmary, Lancs.—Third H.S. At rate of £150.

Bury and District Joint Hospital Board.—Asst. to Med. Supt. £400.

Buxton, Devonshire Hospital.—Asst. H.P. At rate of £175.

Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency Officer. At rate of £130.

Cardiff, City Lodge Institution.—Asst. M.O. £150.

Carlisle. Cumberland Infirmary.—Second H.S. £155.

Carmarthen, Joint Counties Mental Hospital.—Laboratory Asst. £150.

Chailey, Sussex, Orthopædic Hospitals and Schools.—Res. M.O. £250.

Chester Royal Infirmary.—H.S. At rate of £150.

Derby.—Locum Res. Asst. M.O. for Walton Sanatorium, near Chesterfield. At rate of £350.

Doncaster H.S. At rate of £175.

East Lond. *Shadwell, E.*—H.P. and H.S. Each

Exeter, Royal Devon and Exeter Hospital.—Sen. and Jun. H.S. At rate of £250 and £150 respectively.

Freemas *Home, 237, Fulham-road, Chel* te of £250.

Fulham *Hammersmith, W.*—Clin. Asst. At rate of £100.

Glasgow, West of Scotland Neuro-Psychiatric Institute.—Director. £850.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.

Halifax, St. Luke's Hospital.—Jun. Res. M.O. £250.

Hammersmith Hospital, Ducane-road, Shepherd's Bush, W.—Res. Asst. M.O. £350.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.S. At rate of £100.

Hospital of St. John and St. Elizabeth, 60, Grove End Road, N.W.—Res. H.P. At rate of £100.

Huddersfield Royal Infirmary.—Cas. O. and Two H.S's. £225 and £150 respectively.

Hull Royal Infirmary.—Third H.S. At rate of £150. Also H.P. at Sutton Branch Hospital. At rate of £160.

Indian ntments Commission.

Jerusale *Hospital.*—H.S.

Kiddern *eral Hospital.*—H.S. £150.

Kimberl *a.*—Radiologist. £900.

King Edward Memorial Hospital, Ealing.—Sen. Res. M.O. £250.

Lewisham Hospital, High-street, Lewisham, S.E.—H.P. At rate of £80.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Liverpool, Alder Hey Children's Hospital.—Med. Supt. £1000.

London

Middles H.P. £120.

Miller *S.E.*—Out-patient Offi f £150. Also Two H.S.'s and H.P. Each at rate of £100.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Res. Anæsthetist. £300. Also Jun. Surg. Reg. At rate of £150. Also Res. H.P.'s. and H.S.'s. Each at rate of £50.

Northampton General Hospital.—H.S. At rate of £150.

Norwich, Norfolk and Norwich Hospital.—H.S. to Special Depts. £120.

Nottingham General Hospital.—H.S. At rate of £150.

Oldham Royal Infirmary.—H.S. At rate of £175.

Oxford City.—Deputy M.O.H. £600.

Paddington Green, Children's Hospital, W.—H.P. and H.S. Each at rate of £150.

Preston, Lancs, Biddulph Grange Orthopædic Hospital.—Jun. H.S. £150.

Princess Beatrice Hospital, Richmond-road, Earl's Court, S.W.—Cas. O. and H.P. £100.

Queen Mary's Hospital for the East End, E.—H.S. At rate of £120.

Queen's Hospital for Children, Hackney-road, E.—Ophth. Surg. Also H.P. and Cas. O. Each at rate of £100.

Reading, Royal Berkshire Hospital.—H.S. £150.

Royal College of Physicians, Pall Mall, S.W.—Two Leverhulme

land-street, W.— Stanmore. At rate of £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

St. Mary's Hospital, W.—First Asst. Pathologist. £500.

St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C. Clin. Assts.

Salford.—Asst. Res. M.O. for Hope Hospital, Pendleton. At rate of £250.

mary.—Sen. H.S. £200.

Hospital.—H.S. £150.

Jun. H.S. £150.

Staffordshire Royal Infirmary.—Ortho- Also Asst. H.P. £125.

Sudan 720.

Torqua

Tunbri —H.S. £160.

Warrin .S. £175.

West M.O. £350.

Al Each £200.

West End Hospital for Nervous Diseases, Regent's Park, N.W.—Jun. H.P. At rate of £100.

West London Hospital, Hammersmith-road. W.—H.P. and H.S. Each at rate of £100.

Winchester, Royal Hampshire County Hospital.—H.S. At rate of £125.

Woking and District Victoria Hospital.—Res. M.O. At rate of £100.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. and H.S. Each at rate of £100.

Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £150.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Rocester (Stafford).

Births, Marriages, and Deaths

BIRTHS.

HOLDER.—On May 31st, the wife of Dr. S. E. Holder, of Berks Mental Hospital, Wallingford, of

WALSH.—On June 5th, the wife of of Stucley House, Great West-roa a daughter.

WOOD.—On May 29th, at Park Village West, Regent's Park N.W., the wife of Dr. W. Burton Wood, of a daughter.

MARRIAGES.

BOLT—BULL.—On June 4th, at the Parish Church, Hayes, Kent Dr. William V. Dujardin Bolt to Irene, only daughter of Mr. and Mrs. F. H. Bu

LAWSON—HOWARD.—On J -place David Forbes Lawson, oward, daughter of Thomas H d, late of Portland, Dorset.

MANNINGTON—FAWCETT.—On June 2nd, at St. George's Church, Hornsey, R.C.S. Eng., to Ruth, youngest d Fawcett, of Salisbury, and Mrs. Fawcett, Muswell Hill.

ROBINSON—WILLIAMS.—On May 29th, at Benton, Richard Deane Robinson, M.B., B.S., to Freeda, younger daughter of Mr. and Mrs. C. Williams, of Benton, Illinois, U.S.A.

DEATHS.

BATESON.—On June 5th, at Brighton, after a brief illness, Henry Bateson, M.D., L.R.C.P., L.R.C.S., L.R.F.P.S., of Overdene, Southwick, Sussex, and late of Walkden, Manchester, aged 60 years.

BOUTFLOWER.—On June 1st, at Stonecourt, Kersal, Andrew Boutflower, M.R.C.S., in his 88th year.

CHAPMAN.—On May 31st, suddenly at Chatham, Paul Morgan Chapman, F.R.C.P., M.B.E., in his 80th year.

CHRISTY.—On May 29th, in the Belgian Congo, Cuthbert Christy, M.B., C.M., late Major R.A.M.C., of Chignal St. James, Chelmsford, in his 69th year.

CRUICKSHANK.—On May 29th, at Naylor House, Larkhall, S.W., James Burr Cruickshank, M.B., Ch.B., son of the late Peter Cruickshank, M.A., Tarves, Aberdeenshire.

DE CHAZAL.—On June 2nd, in London, Edmond Lucien de Chazal, M.D. Lond.

GARSON.—On May 31st, at Ewell-grove, Ewell, Surrey, John George Garson, M.D. Edin., L.R.C.S. Edin., in his 78th year.

GRANGER.—On June 2nd, at Fron Haul, Bodfari, Farington Marsden Granger, M.R.C.S., L.R.C.P. (late of Chester).

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE SAFETY OF PEDESTRIANS

LORD DANESFORT'S BILL.

THE Road Traffic (Compensation for Accidents) Bill, sponsored by Lord Danesfort, which won a second reading on June 2nd by 22 votes to 8, proposes to make the motorist liable for traffic casualties irrespective of any question of his negligence. The Bill has no chance of becoming law this session, but its supporters were by no means confined to those who dislike all forms of mechanical transport or who, like Lord Buckmaster, have unfortunately been the victims of accident themselves. Lord Buckmaster's Road Traffic Bill, read a second time last April, sought to increase criminal penalties. Lord Danesfort's Bill merely proposes to extend civil liability and compulsory insurance. It is a Bill for pedestrians and pedal cyclists; it does not apply to accidents between two sets of motorists—because motorists are already compulsorily insured and will be looked after, according to Lord Danesfort, by the insurance companies. Advocates of a change in the existing law can point to the appalling loss of life under present conditions—7300 persons killed in 1930 (over half of them pedestrians), not to mention 178,000 persons injured. Graphic comparisons have been made with the total casualties of the Boer War or of the Battle of Waterloo or with the epidemics of the past, but indeed the figures speak for themselves. Motorists, says Lord Danesfort, are always insured; they have to be, by statute. The pedestrian is seldom insured, and therefore must fight a powerful insurance company which will naturally raise all possible defences. The plaintiff's first obstacle is his duty to prove the driver's negligence. If the pedestrian has been killed, the main witness is removed; if he is seriously injured, his recollection will be confused and imperfect; it may be difficult to produce other witnesses. Thus the plaintiff may be driven to accept what compensation the insurance company may offer rather than fight a long, costly, and doubtful battle.

Even when the plaintiff has proved the driver's negligence, there is a further obstacle in the defence of contributory negligence—a highly technical matter. Parliament, says Lord Danesfort, owes the pedestrian some protection because it has changed the law and now allows the motorist to travel at speeds which, but for the change, would have been impossible. The legal and legislative analogies to the proposed principle of compensation without proof of negligence have already been mentioned in our columns (THE LANCET, March 19th, 1932, p. 629). Other European countries have adopted a similar rule of liability though they vary in the defences they permit. Lord Danesfort's Bill makes an exception where the injury is caused by the negligence of the person injured. He hinted he would not mind amending his Bill to allow another exception (as in some continental countries) in the case of *force majeure*. The Lord Chancellor seemed willing to accept the principle of the absolute liability of motorists. He found an analogy in the legal doctrine that a man keeps a lion or a tiger at his peril; if the animal is taken out upon the highway and escapes or gets out of control, there is liability for consequent injuries irrespective of negligence. Lord Sankey seemed ready to fix motorists with the onus of establishing some lawful defence, but he wanted further examination of the defences available. So much for the legal aspect of the Bill. The practical issue is a matter for the insurance companies. How much will they increase their rates of premium on policies complying with Part II. of the Road Traffic Act? A new class of accidents will be ranking for compensation and the opportunities for unscrupulous claims will be multiplied. The ordinary arguments against the Bill will readily occur to motorist's minds. It is unfair to make a defendant prove his innocence; it is unreasonable to have one liability for the motor-car and another for the farmer's gig; the motorist is already taxed heavily and should be spared further imposition; the average driver is a careful man and not a wild animal; and pedestrians should not be encouraged to sally forth with no sense of responsibility. Earl Howe doubted if many pedestrians are acquainted with the admirable Highway Code issued by the Ministry of Transport. And there is much to be said for Lord De Clifford's plea that the division of road-users into motorists and pedestrians, almost on the lines of class-warfare, is unfortunate and should not be fostered. The Earl of Plymouth, as the mouth-piece of the Ministry, supported the second reading of the Bill but declined to commit the Government to its terms.

In the Memorandum prefixed to his Bill, Lord Danesfort claims that his proposals will help the hospitals by indirectly extending the scope of Section 36 (2) of the Road Traffic Act. The Act has been of such meagre use to the hospitals that they may hardly be interested in the extension. Viscount Cecil read to the House an extract from the Poplar Hospital report which declared that the first year's working of the Act must be taken to indicate that motoring accidents to children are always the child's fault, "for in no single instance has the Hospital's account for the child been paid." If this means that in no single case has a child been able to prove the motorist's negligence, the implications of the statement will confirm many in their support of the Bill. The position of the hospitals in relation to traffic casualties is, of course, a separate problem in itself. Lord Danesfort's Bill, in its endeavour to simplify and shorten its proposals, leaves this problem untouched.

SEX RESEARCH

THE Proceedings of the Second International Congress for Sex Research, edited by Mr. A. M. Greenwood, have been issued in book form.[1] The volume contains 40 papers in English, 21 in German, 11 in French, 7 in Italian, and 1 in Spanish. It is divided into five parts, headed biology, hormones, therapy, contraception, and sociology, each of which covers a very wide range of subjects. Only a small number of these will be of interest to the medical reader. Nearly 200 pages are devoted to a discussion of hormones, but few of the papers have clinical bearings. Of the twelve chapters in the section on therapy, five are in English. These relate to the clinical use of testicular and ovarian hormones, the constitutional factor in human sterility, and the relation of gonorrhœa to marriage. The subject matter of the two papers on contraception contributed by Mr. J. R. Baker and by Mr. C. I. B. Voge has already been discussed at various times in our columns. Though the preparation of an index would have presented formidable difficulties, in view of the different languages in which the papers are written, it would have repaid the trouble expended upon it.

THE SIGNATURES OF PLANTS

IN a case which came up for consideration at the recent meeting of the General Medical Council it was stated. concerning a certain remedy, that a large number of people were employed in collecting the raw material all over the country, at a high expense, while the necessary substance could only be obtained at certain times of the year. The inference is that the remedy is manufactured from plants or a plant, and it is in accordance with custom, where the composition of a therapeutic substance is to remain secret, that we are told that the collection of supply is made expensive because of the rarity of the plants or the obscurity of their habitat. Without assuming that the therapeutic value of our domestic flora has been so well investigated that no plant of any potency remains to be discovered, it is at least unlikely that such is the case, for British botany has been very thorough over a long period. Moreover, the actual value of herbal derivatives has been considerably worked at since the war, when investigations were made to discover if the British Pharmacopœia could be reinforced within our own borders, where circumstances would prevent us from relying upon foreign sources. So that to a considerable extent we can now rely upon scientific trials for estimates formed of the value of any domestic plants.

The popular and almost age-long estimates of the efficacy of certain common plants have been undergoing radical alteration for a hundred years, but an old fame still clings to them. And this has been in some cases due to the influence of symbolism. For the repute of these plants was not infrequently due to what is termed their "signature" and the phrase was often on the lips of bygone herbalists, who were not always consistent in their use of it. Properly speaking, "the signature of a plant" is the possession in any of its constituent parts of some shape or quality suggesting medical employment. In this manner pharmacological claims were supposed to be symbolised. As examples where some characteristic feature of a plant has been regarded popularly as an indication of its therapeutic influences may be mentioned the leaves of the liverwort, a decoction of which has been relied upon as a remedy in hepatic disease; the markings on the inflorescence of euphrasia which dictated its use as an astringent eyewash; and the corolla of prunella. which looks faintly like a bill-hook, wherefore its fomentations have been much esteemed in wounds received by hedgers and ditchers. Similarly certain plants have been regarded as a remedy for pulmonary ailments because their spotted leaves resembled a diseased lung. Sometimes a plant would receive a popular name because of its supposed qualities, and sometimes the popular name would suggest the supposed qualities. "Henbane," for example, is a corruption of "hanging bell," but no one doubts that the name implies that its poison has a particular threat for poultry. Other examples could be adduced of the way in which these popular beliefs have influenced the nomenclature of the hedge-row, and it is just possible that the real medical efficacy of some British herbs may remain to be detected, serious trials not having been made in face of the ancient superstitions.

MALE IMPERSONATORS

THE novel has again made use of the difficult theme the woman in male attire who leads a man's life. Miss Johnstone's heroine ("The Maiden," London: John Murray, 7*s.* 6*d.*) is a pirate and, with reservations, a thoroughgoing pirate until a change of heart comes over her. The story is well told and worth reading. There is possibly an unconscious reason for making the male impersonator into a pirate, as there are several historical precedents. Notably at the beginning of the eighteenth century two women, named Mary Read and Ann Bonney, lived as pirates, but probably as the mistresses of male adventurers; while in the list of women who for one reason or another have donned the habits and imitated the ways of men, it is a curious fact that the sea has always possessed a fascination. The histories of Ann Jane Thornton and Mary Ann Talbot are quite well known, and each managed successfully to conceal her sex for a short period, but none kept up the mystery so completely as James Barry, to whom frequent allusion is made as a female member of the Army Medical Staff. James Barry, whose real name has never been disclosed, though it is suggested that legally she had no name, was a medical student at Edinburgh a century ago, when feminine characteristics in appearance and gait were noticed by other students, but apparently there was nothing sufficiently striking about her female traits to interfere with admission to the Army Staff. In this service she became a prominent person. Some 30 years ago there was considerable correspondence in the columns of THE LANCET turning on her strange history, when several of her actual acquaintances gave descriptions of her appearance, supplying evidence that, in spite of her male attire and military rank, it was a matter of common repute that she was a woman. Reference to Hart's Army List for the year 1865 shows that the name "James Barry" stood at the head of the list of Inspectors General of Hospitals, and in July of that year the *Times* announced the death of "Dr. James Barry," and, later, the fact that it had been officially reported to the Horse Guards that the doctor was a woman. James Barry was said to be the illegitimate daughter of an important peer, and to owe his commission and his official positions in the Service to aristocratic friends, at the same time there appears evidence that she was skilled in her profession. It is noticeable that neither in her case nor in that of any of the marine or military adventurers does there seem any suggestion of sexual perversion. Even in the story of Hannah Snell, who was wounded when serving as a marine, it was always held that this element was wanting, though as "Samuel Bundy" she went through a form of marriage with a woman, and, after discharge from the Navy, the couple lived for years as shopkeepers in the East of London.

PROPHARMACIENS

To the Editor of THE LANCET.

SIR,—I should be glad if one of your learned readers would kindly supply a definition of the words "Propharmacien" and "Médecin Propharmacien." I cannot find these words in my dictionary and I am curious to learn what kind of post this is in France. The words occur in four consecutive advertisements in the current issue of the *Siècle Médical*.

I am, Sir, yours faithfully,

June 2nd, 1932. TRANSLATOR.

DR. W. HOWARD JONES writes: A letter in the *Daily Telegraph* of June 2nd commenting upon the rewards of hospital consultants, over a name identical with mine, has in some quarters been wrongly attributed to me. I shall be grateful if you will enable me to disclaim all responsibility for this letter.

UNDER the will of Sir Dorabji Tata, who has died in Bavaria, it is understood that a large sum of money will become available for medical research. Before leaving India last April he executed a trust deed covering property worth three crores of rupees (£2,250,000) which will be used mainly for charitable purposes. In addition he set aside 25 lakhs (£187,000) for instituting scholarships for the investigation of diseases at present regarded as incurable. Sir Dorabji, who was chairman of the Tata Iron and Steel Works and many other undertakings in Bombay, was an honorary Fellow of Caius College, Cambridge, where he was formerly an undergraduate.

ADDRESSES AND ORIGINAL ARTICLES

THE REACTIONS OF THE EYE TO GENERAL DISEASE *

BY F. A. WILLIAMSON-NOBLE, M.B. CAMB., F.R.C.S. ENG.

SSISTANT OPHTHALMIC SURGEON TO ST. MARY'S HOSPITAL, AND TO THE NATIONAL HOSPITAL, QUEEN-SQUARE; ASSISTANT SURGEON TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL

IT has often seemed to me that the eye affords pportunities for the study of disease which are iven by no other part of the body. Thanks to the lit-lamp and corneal microscope, its anterior layers, s far back as the front portion of the vitreous, are ccessible to observation under a magnification s high as 40 diameters, while the fundus of the eye s seen, with the ordinary ophthalmoscope by the irect method, under a magnification of 14 diameters wing to the lens system employed by Nature.

The eye seems to constitute a pathological laboratory ith a clear window through which we can watch he changes in health and disease undergone by living issue in its natural surroundings. When we emember that the optic nerve and retina are morphoogically portions of the brain, the importance of the phthalmoscope becomes still more evident, since ve have actually exposed to our view a portion of the orebrain which can be examined during life with the tmost ease under a magnification of 14 diameters.

What are the changes, then, that are thus revealed o us in various diseases? There are two ways of nswering this question. One is to take the structures f the eye seriatim and enumerate what happens vhen they are attacked by disease, and the other is o take each disease separately and describe what appens when it attacks the various parts of the ye. The former method seems to me to savour too nuch of the text-book, while the latter would entail nuch repetition, so I trust you will allow me to take he middle course as being the more useful. I have o wish to make my remarks encyclopædic and would refer to be eclectic, picking out from the mass of ccumulated data of medical ophthalmology those eatures which I think are of interest.

Measles

To take, first of all, a very ordinary disease: neasles. It is a commonplace of medicine that the yes require considerable care during the course of his malady, owing to the constant occurrence of onjunctivitis in varying grades of severity, possibly vith corneal ulcers as a complication. It is not robably realised, however, what an intimate relationhip this disease has to the onset of convergent squint n children. The number of cases of squint which late from an attack of measles is really quite large, nd the reason for it is probably as follows.

Non-paralytic convergent squint unassociated with lisease of the retina or optic nerve is due in the ltimate analysis to failure of the fusion centre to orrelate the movements of the two eyes. Most of hese cases occur in hypermetropes and, if the hypernetropia is not corrected with glasses, clear vision an be obtained only by accommodation. The ynergic action of convergence tends to occur at the ame time and, if the fusion power be weak, little or no diplopia is caused and one eye becomes turned in. Binocular vision is a relatively late phylogenetic acquisition and is therefore a function which is easily upset. An analogy with this is to be found in the action of anæsthetics on the central nervous system, in which the highest centres are those to be first affected. An even closer analogy is perhaps to be found in the action of alcohol, over-indulgence in which is traditionally supposed to bring about diplopia and in extreme cases even polyopia. Be this as it may, the toxin of measles seems in a fair number of cases to have some peculiar selective action on the fusion centre in the brain, and to bring about concomitant convergent squint, apart entirely from anything in the way of encephalitis.

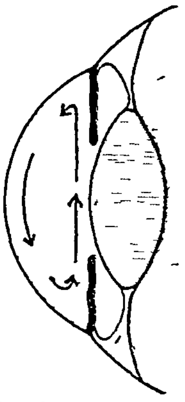
Another sequel of measles, though an uncommon one, is a degenerative change in the macular region of the retina which brings about marked diminution of visual acuity. Here again the phylogenetic theory may come in, since macular vision is a relatively late acquisition.

Reactions of the Iris and Ciliary Body

After this introductory digression, I should like to become a little more systematic and describe some of the reactions of the iris and ciliary body to general disease. These parts must be considered together, as they are structurally continuous with one another. Iritis can be caused by various types of blood-borne infection, the commonest agents being the spirochæte, the gonococcus, and the various forms of streptococci associated with focal infections of the teeth, tonsils, alimentary or genito-urinary tracts, and sinuses. In my experience the first sign of involvement of the iris and ciliary body in an inflammatory process is slight opacity in the aqueous and the occurrence of fine precipitates on the back of the cornea.

Everyone is familiar with the effect of a beam of sunlight passing through a partially darkened room: how it shows up all the motes of dust which are otherwise invisible in the air. The same principle can be applied to examination of the anterior chamber. By means of the slit-lamp, a narrow pencil of rays can be directed obliquely through the aqueous and its path can be observed by a binocular microscope placed opposite the eye. In normal circumstances the aqueous is "optically empty": the fluid contains no particles and so the path of the ray of light is invisible. If there is the slightest turbidity, however, the beam becomes visible, and this so-called aqueous flare is one of the earliest and most reliable signs of inflammation of the iris and ciliary body. Close examination reveals a very interesting movement of the particles. The cornea is in contact with the air, and is therefore cooler than the iris. Hence the fluid in contact with the posterior surface of this membrane is cooler than that in contact with the iris. A thermo-syphon effect results, analogous with the cooling methods employed in some motor-cars, so that the aqueous is kept in constant movement and the particles in the anterior part of the aqueous are seen to be descending, while those in the posterior part, near the iris, are ascending. Fig. 1 shows the direction of the currents.

FIG. 1.



Circulation of the aqueous in the anterior chamber.

---

* The first Lettsomian lecture for 1932, delivered before the ledical Society of London on Feb. 29th. The second and third ectures will be published in coming issues.

Clinically, circumcorneal flush is an extremely valuable sign, even though unattended by pain or any definite obscuration of vision. Experience with the slit-lamp has taught me that, in the absence of glaucoma or some inflammatory affection of the cornea, injection of the conjunctiva in the region of the corneal margin means iritis or iridocyclitis, even if nothing can be seen by the ordinary methods of examination. If effective treatment can be instituted at this early stage, there may be complete recovery without any of the usual sequelæ of iritis, such as adhesions of the iris to the lens, spots of pigment on the posterior surface of the cornea, opacities in the vitreous, and membranes on the front of the lens.

CHARACTERISTICS OF IRITIS

Whether the primary cause of iritis is bacteria or their toxins is still a matter of dispute, to which I shall refer again later; the immediate question is the structural changes occurring as a result of the arrival by the blood stream of micro-organisms or their products. The first change is, of course, engorgement of the blood-vessels with œdema of the tissue, and the second the occurrence of cellular infiltration and the formation of exudate. The former is not apparent in the iris itself in the earlier stages of the disease, but is shown indirectly by the circumcorneal flush and by the contraction of the pupil brought about by swelling of the iris, though this is possibly aided by reflex spasm of the sphincter. Exudate is visible in the very early stages only when the slit-lamp is used, but later is manifested as a more obvious haze in the aqueous, often accompanied by a collection of inflammatory products at the bottom of the anterior chamber and on the back of the cornea. The formation of exudate is also responsible for the adhesions of the iris to the underlying lens and the formation of membranes over the front and back of this structure.

Various modifications may occur: one, particularly important clinically, in cases of syphilis, is localisation of the infection to a relatively small area of the ciliary body with subsequent gummatous degeneration of this organ and of the overlying sclera. The importance of the condition is twofold. First, if it be allowed to progress, the sclera will perforate and the eye be lost. Secondly, the only obvious clinical manifestation may be the occurrence of an elevated pinkish-red area on the sclera adjacent to the limbus, similar to the benign condition known as episcleritis.

I well remember a case of this type I had at hospital once:

A man came up with a small reddish-pink area on the sclera, at about "12 o'clock." It looked like episcleritis, but slit-lamp examination showed the presence of a few fine particles in the aqueous, though there was no clinical evidence of iritis. I therefore had a Wassermann test done; it was strongly positive and the swelling rapidly resolved under antisyphilitic treatment. When the iris *is attacked by the toxins or organisms of gonorrhœa* or of focal infection the course is usually more acute.

It is now generally agreed that the aqueous is formed by a process of dialysation from the blood. The capillary vessel wall forms a semi-permeable membrane which allows the smaller crystalloid molecules to pass through but not the large protein ones, the osmotic pressure of the proteins of the blood being thus in large measure responsible for the maintenance of intra-ocular pressure. In the acute types of iritic infection, the aqueous has a high protein content and is almost gelatinous in consistence. This is shown particularly well on slit-lamp examination by an absence of the circulatory movement in the particles. In some cases, particularly gonococcal, the gelatinisation of the fluid is so marked that it makes it look as though the lens were dislocated into the anterior chamber, and there have been cases when this mistake in diagnosis has been made. It is tempting to assume that in these cases some damage is done to the endothelial lining of the capillaries by the gonococcal toxin, so that the protein molecules can pass through.

It is interesting to note the long latency of the gonococcus. The attack usually occurs at the time of the arthritis and often not for years after the initial urethral infection. This may be because it takes a long time for the infection to become generalised, but it also seems as though there were some anaphylactic element whereby the iris becomes sensitised to the actions of the toxin. Relapses are frequent, but they usually occur in the same eye, and if a cure is to be effected by vaccines they must be administered for a very long period. A case I had some little time ago illustrated this sensitiveness of the iris rather well.

He was a man aged 50, and prolonged vaccine treatment, combined with iridectomy, had sufficed to rid him of his trouble. A year or so later he returned with a tremendous attack of acute iritis which had come on after prostatic massage at one of the genito-urinary hospitals. Nothing violent had been done, but presumably a few gonococci or their toxins had been forced into the blood stream and the sensitised iris had immediately reacted. The prostate was then removed, and no further attacks occurred. This treatment is possibly a little heroic for gonococcal iritis, but it was certainly effective.

Focal Infection

The type of iritis produced by focal infection usually bears a close resemblance to that caused by the gonococcus. It is subject to relapses, may remain unilateral for a long time, and usually results in the formation of narrow adhesions between the iris and lens, in distinction to the syphilitic type of iritis which is commonly bilateral and causes broad adhesions. These cases of iridocyclitis due to focal infection are at times extremely difficult to diagnose. The fall into three groups:—

1. The acute type, with a reaction resembling that seen in the gonococcal cases, though the aqueous is not usually so gelatinous.

2. The chronic type with subacute remissions.

Such a case is an aged lady who comes to see me periodically and has been under the care of three generations of ophthalmic surgeons. I am not discussing treatment, or I might tell you of all the things that have been done to her. Suffice it to say that, in spite of many and varied kinds of treatment, she still has attacks of mild cyclitis at intervals of a few months, in which the eye becomes a little flushed and a few fresh spots of precipitate form on the back of the cornea. In spite of this, on her good days, she still has 6/9 vision in one eye, the other eye having developed cataract and a dislocated lens after iridectomy performed many years ago.

3. The really chronic type. In this, there is usually no injection of the circumcorneal region of the conjunctiva, but examination of the eye reveals the *presence of small dots of precipitate* on the back of the cornea. The iris is usually discoloured owing to absorption of pigment by the phagocytic cells constantly present in its stroma, and the lens becomes slowly opaque from defective nourishment, owing to toxicity of the aqueous.

An interesting feature in many of these cases is paralysis of the sympathetic on the affected side. This is shown by the pupils being approximately equal in bright light but markedly unequal in light of reduced intensity, the pupil on the affected side being the smaller, owing to paralysis of the dilator fibres of the iris. The inequality is made still more manifest by the instillation of cocaine. It is a nice point, and one which has *not yet been decided*, whether he sympathetic paralysis is the primary cause of the yclitis. If there are such things as trophic fibres, nd if their course to the eye is via the sympathetic erves, then interference with these nerves will educe the resistance of the iris and render it more able to bacterial invasion.

The whole question of the relation of focal infection o eye disease is to my mind still in the melting-pot. n England and America many ophthalmologists are pt to explain otherwise obscure cases of chronic intra-cular inflammation as due to the action of metastatic eptic foci, and in a fair number of cases they are undoubtedly right, while on the Continent, and particularly in Germany, these lesions are far more commonly ascribed to the action of the tubercle bacillus. One recent writer on ophthalmic pathology [1] has put the matter rather nicely by saying that "an uninitiated reader of the literature might easily be led to suppose that in Germany, and elsewhere on the Continent, tuberculosis is quite a different disease from that which we find in this country, while on the other hand the teeth and tonsils of the British and American people were in some obscure way stimulated to most malicious behaviour." The truth must, of course, lie between these two assertions, though Wright and his co-workers have recently been doing some interesting work on tuberculin. This was the subject of a paper read before this society, so I need not go into the details beyond saying that the experiments showed how increased immunity to organisms such as the staphylococcus could be brought about by the administration of tuberculin. One is not therefore justified in saying that a case of iridocyclitis or choroiditis is tuberculous because the condition improves with tuberculin treatment.

ENDOCRINE FACTORS

Another factor to be considered is the endocrine system. Let me give an illustrative case before discussing the matter further.

A woman, aged 59, was sent to see me from the country with a history that the right eye had become blurred and bloodshot a month previously. Vision of this eye with glasses was only 6/18, while that of the left eye was 6/6 partly. The tension of each eye was raised well above the normal figure of 15–25 mm. Hg, that of the right being no less than 60 and of the left 47 mm. Hg. There was evidence of slight inflammatory change, in the shape of a few dots of precipitate on the back of the right cornea. No evidence of focal sepsis was forthcoming, beyond the presence of a crowned tooth which was removed without affecting the eye condition. It became evident that if nothing were done, the sight, at any rate of the right eye, would be lost. Miotics were ineffective, so I performed an iridectomy, with the double intention of warding off iritis and of reducing the intra-ocular pressure to normal. Recovery in the right eye was uneventful, and 6/6 vision with glasses was attained, but during her stay in the nursing home the patient complained of hæmorrhoids. I thought that this condition was at the wrong end of the body for me, so asked a very able general practitioner of my acquaintance to come in and see her. He prescribed the necessary ointments with satisfactory result but, more important still, told me that the patient looked as though she were suffering from hypothyroidism, and asked if I would agree to putting her on thyroid extract. I did so, with the result that the tension in the unoperated eye gradually came down to normal, vision with glasses came up to 6/6, and the one or two small spots of exudate on the back of the cornea slowly absorbed.

It seems to me, therefore, that in chronic iritis and cyclitis many factors may be involved. First there are the actual causative organisms. The crux of the matter, to my mind, hangs on the word "causative." In other words, why do these organisms cause the iritis ? Most of us probably have, somewhere in our bodies, hidden foci of infection, and we do not develop iritis. I possess, for example, a couple of crowned teeth, and I believe my tonsils are not above suspicion, but so far they have not occasioned me any inconvenience. It seems conceivable, however, that if the thyroid mechanism were to break down under the continued onslaught of chronic sepsis, as in McCarrison's fishes, or from some other cause, a vicious circle might be established and various forms of inflammatory change become manifest. We are not right, therefore, in always attributing the occurrence of these cases solely to micro-organisms. In the case I was mentioning there seems little doubt that thyroid insufficiency was also a cause, and that the simple fact of giving thyroid extract was enough to put the patient right.

ANAPHYLAXIS

Another point of view is the anaphylactic one—I can perhaps best explain what I mean by analogy.

I remember, when a student in the dermatological department at St. Mary's Hospital, seeing a man with a violent eczematous sort of condition of his forearm. He gave a history of having worked in sandal-wood for many years—I think it was about 20. He had never had any trouble until recently, but now the slightest trace of sandal-wood oil was sufficient to cause him dermatitis and he wanted to know what to do about it.

A similar condition is always cropping up in eye work—namely, atropine irritation. A patient may use atropine for weeks in the treatment of a chronic iritis and then, suddenly, the lids and adjacent skin of the face will become swollen and red, so much so that I have known the condition to be diagnosed as erysipelas. It entirely subsides on withdrawing the atropine, but reappears if the drug is instilled into the eyes again. It seems likely that the iris may become similarly sensitised to the action of certain bacteria or toxins, so that a patient with irides of this type would produce an inflammatory reaction with a very much smaller dose of organisms than one whose irides were normal. It is for this reason that I always like to use small doses of vaccine rather than large ones, at any rate in the early stages, because it seems to me that what we have to do is to desensitise the patient before we can hope to start on immunising him. A similar reasoning has been applied by some, notably Derby and Walker, Iggersheimer, Schoenberg and Wesseley, to the ætiology of interstitial keratitis.

The cornea illustrates the effect of the anaphylactic factor rather well. The last named of the above observers [2] injected one or two drops of inactive beef or horse serum into the tissue of the cornea. There was a little reaction, which all passed off in a few hours. Some eyes showed no further change, but in others, after 12 to 14 days, there was some injection followed by a progressive opacity in the deeper layers of the cornea, sometimes with vascularisation. If at this time a small quantity of serum were introduced into the cornea of the other eye, the characteristic interstitial inflammation developed within 24 hours instead of within 12 to 14 days. A variation of the experiment was to give 4 c.cm. of serum intravenously at the end of 14 days. If the injected eye had not already developed interstitial keratitis, it did so within 24 hours, and if it had previously developed keratitis, the inflammation became more severe.

These experiments have been applied to the elucidation of human interstitial keratitis in the following manner. It has been proved, histologically, that spirochætes can wander into the cornea in congenital syphilis without producing any notable reaction. Their presence, however, or the presence of their toxin, may be enough to sensitise the cornea. If now, at some period of the child's life, the general resistance becomes lowered—through, say, one of the exanthems—the spirochætes latent in some part of the body may again become active and the eye, previously sensitised, will speedily react.

The same effect may follow local trauma to the eye, and many cases of interstitial keratitis date the onset of this disease from some minor injury to the cornea such as that produced by the entry of a foreign body. Such cases are very difficult when the question of compensation arises. No definite opinion seems to have been expressed yet as to whether interstitial keratitis following a blow or injury to the eye can be regarded as attributable to this or not.

The anaphylactic theory also helps to explain the resistance of the disease to treatment. On the whole, a case treated with antisyphilitic remedies runs a more benign course than one which is not so treated, but on the other hand, it is not very uncommon for interstitial keratitis to break out in the unaffected eye while the patient is actually under general treatment for syphilis. If only a small quantity of antigen is required to provoke the anaphylactic reaction, such a course of events can be easily understood.

ELECTIVE LOCALISATION

Another point bearing on this aspect of the ætiology is the work of Rosenow on the elective localisation of bacteria. The theory is that organisms become accustomed to certain conditions for growth and do not grow except under these conditions. Oxygen tension is an important and variable factor, and it is thought that organisms will attack another part of the body if they can find there the same oxygen tension as obtained in the original focus. The most striking confirmation of this theory of elective localisation has been provided by Benedict. He grew streptococci from the teeth of five patients suffering from acute iritis, due presumably to dental infection, and injected them intravenously into rabbits, with the result that material from four of the patients produced iritis. On the other hand, streptococci grown from the teeth of nine patients suffering from chronic iritis failed to produce any ocular lesions on intravenous injection into rabbits. I am not a bacteriologist, and so am not in a position to say what it is that makes the microbes do this—whether they become, so to speak, habituated to certain conditions in the teeth which are also present in the eye so that they can migrate there and continue to live, or whether a new strain which has this property is implanted on the old ones. The reaction seems to be a fairly delicate one, however, and to occur only at certain stages of virulence. Thus Rosenow,[3] on passaging a strain of pneumococci through rabbits, found that at the eighteenth passage they produced suppurative conjunctivitis, at the nineteenth iritis, and at the twentieth marked conjunctival and scleral hæmorrhages, while subsequent passages failed to produce eye lesions. A similar result was obtained with another strain at the tenth and fourteenth passages, and the same kind of thing occurred with *B. coli* and with staphylococci. The injections were made intravenously, and an interesting feature was the association of lesions in other parts, such as the appendix, joints, stomach, pericardium, and kidneys, with the injections which affected the eyes. Perdreau has found a similar phenomenon with herpes virus in the production of encephalitis by passaging.

From the ætiological standpoint, it is perhaps worth while to have some figures bearing on the relative frequency of the various causes of iritis. Numerous tables of this kind have been published, one of the earliest being by Arlt, as long ago as 1853. The latest, and probably the most reliable, is that by S. R. Gifford.[4] His total number of cases was 118, and of these 22 per cent. were of tonsillar and 16·9 per cent. of syphilitic origin, 12·7 per cent. were due to infected teeth, 8·5 per cent. to combined infections, 6·8 per cent. to sinusitis, and 6·8 per cent. to gonorrhœa. Of these 5·1 per cent. were attributed to prostatic infection, 1·7 per cent. to pelvic infection in women. A further 1·7 per cent. were diabetic, while in 16·1 per cent. no cause was found.

This division agrees fairly well with my own impression of the causes of iritis, though possibly the tonsillar figure is rather higher than one would expect. Gifford's figures were, however, very carefully compiled, and in cases where more than one possible cause was present, the one mentioned as the ætiological factor was that of which the removal was followed by complete relief of symptoms.

Syphilis

Syphilis and tuberculosis are two fairly common diseases, and I should like to say a little more about the reactions to them of the iris and ciliary body. From a purely ophthalmic standpoint, one would say that iritis is a fairly common complication of syphilis, but on going into the figures it appears that only from 0·42 to 5·37 per cent. of syphilitics acquire iritis during the course of the disease, though probably double this number have involvement of some part of the eye, since Groenow found that among 2000 patients with syphilitic ocular disorders 45 per cent. had iritis.

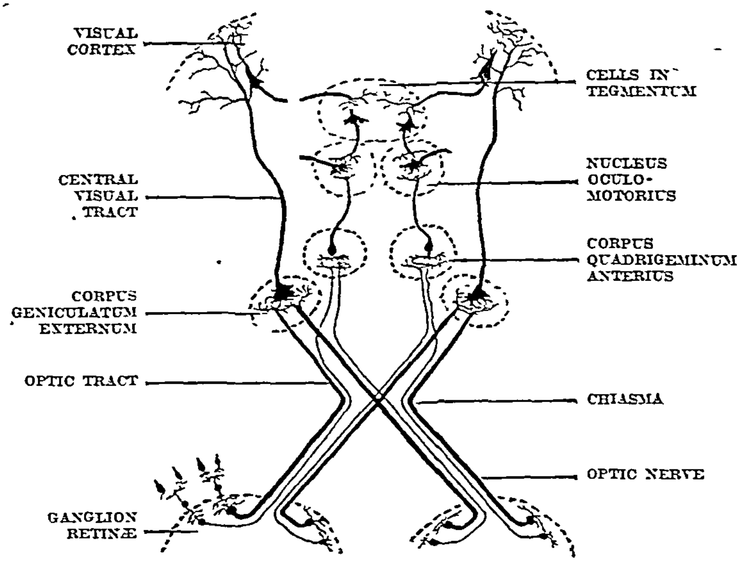
The iris may be involved in the course of the disease or possibly as the result of faulty treatment. If, for example, in a case of well-established untreated syphilis, arsenicals are vigorously used in the early stages, a large number of spirochætes are killed, their toxins are liberated, and a Herxheimer reaction is produced which may involve the iris. I remember this happening to a patient of mine at hospital who had quite a mild syphilitic iritis. He was sent to the venereal disease department of another hospital, where he was given a full dose of novarsenobillon, with the result that the iritis became much more violent, though it eventually quietened down under continued treatment. On the other hand, if efficient treatment is begun early but is not continued for a long enough period, the iris is very liable to a *rezidiv* reaction, since it and the uveal tract, in common with the central nervous system, are slow to develop natural immunity. If, therefore, the normal inflammatory response has been aborted by the early use of antisyphilitic remedies, the few spirochætes that remain after treatment has ceased will find, so to speak, a virgin soil and grow apace, with the production of severe iritis. It is worthy of note in this connexion that spinal fluid findings indicate a higher percentage of neurosyphilis in patients with iritis than in those without it.

From the diagnostic standpoint, it is unfortunate that the reaction of the iris to syphilis is not always the same, and quite frequently it is impossible to distinguish an iritis due to this cause from an iritis due to one of the many others. It may be comforting, however, especially to those whose field of action is not limited by the bony margin of the orbit, to know that nearly all the cases of early iritis in a recent survey[5] have had other recognisable signs of secondary syphilis, though sometimes these had to be looked for carefully.

Typical syphilitic iritis does, however, occur and so merits a short description. It is characterised chiefly by the appearance of one or more nodules at the pupil margin or at the periphery of the iris which vary in size from that of a hemp seed to a small pea id in colour from yellowish to reddish-brown. he intervening iris is comparatively unaffected. hese nodules are not gummata and soon clear up ider treatment, but the latter may develop in the rtiary stage of the disease in the same way as they in the ciliary body. They are then considerably rger, are solitary and, when they break down, ave an area of atrophy in the iris.

Late syphilitic iritis is not so easy to diagnose, nce it is, of course, obvious that syphilitic patients ay easily develop iritis from other causes, and mmermann[6] estimates that in 6·7 per cent. of itients with supposed syphilitic iritis and a positive 'assermann reaction the ætiological factor is one ther than philis. Also it is t uncommon in te syphilitic tis, as in other te manifestations of this sease, to find at the Wassermann reaction is gative. In a cent survey[5] the 'assermann reac- n was positive 97 per cent. of ses of early tis, and 55 per nt. of recurrence ses, 81 per cent. which had late philitic iritis. he therapeutic st ought to be liable, but even is is open to llacies for two asons :—

FIG. 2



Relations of nerve cells and fibres of visual apparatus. (Schafer.

1. Late syphilitic sions, particularly if they involve the cornea, are notori- sly difficult to cure as quickly as syphilitic lesions sewhere.

2. Many cases of non-syphilitic iritis are benefited by course of arsenical antisyphilitic treatment. An instance this was the old lady I mentioned earlier who had suffered om iridocyclitis for many years. On two occasions I have dered her a course of six injections of N.A.B., and each time e inflammatory symptoms disappeared and did not recur r some months.

THE ARGYLL ROBERTSON PUPIL

The association of syphilis with the iris inevitably ings up the problem of the Argyll Robertson pupil, ne of the many vexed questions of neurology. I not propose to go into it at all deeply, because to so would take up at least one whole lecture and ould entail a wide excursion into the anatomy of the ntral nervous system. In a recent publication by innier Wilson,[7] from which I have gleaned much seful knowledge, he cites no fewer than 72 references, that the subject is a large one. So many conflicting pinions have been held at one time or other, however, at I feel it is worth while to say something on this bject, especially as some recent work, and in articular some cases cited by Wilson himself, have one much to clarify the pathology of the condition.

In the first place, what exactly is the Argyll obertson pupil? It seems to consist essentially in ne absence or a marked diminution in the reaction the pupil to light with preservation of its reaction accommodation-convergence. There may or may ot be associated myosis, and the consensual reflex to light on illuminating the fellow eye may or may not be present. The lesion is to be regarded as the consequence of destruction, whether by toxins, new growth or trauma, of a certain part of the pupillo-reflex arc. It would therefore follow that, although the Argyll Robertson pupil is in a high percentage of cases due to neurosyphilis, it is not necessarily pathognomonic of this disease.

It may be of service to mention other diseases in which it occurs, though these are well known. First and foremost is lethargic or epidemic encephalitis, a disease which is particularly interesting, since some cases of it show the reversed Argyll Robertson phenomenon—i.e., reaction to light and none to accommodation-convergence. Secondly, it has been found in cases of disseminated sclerosis, and in syringomyelia and syringobulbia, while chronic alcoholism has also been known to produce it. Most interesting of all, however, from the pathological standpoint are the cases of cerebral tumour which are associated with an Argyll Robertson pupil. A sufficient number of cases would now seem to have been published to establish the truth of the observation that tumours in the region of the third ventricle, aqueduct, or anterior corpora quadrigemina may give rise to this type of pupil reaction. In particular, injury of the anterior corpora quadrigemina appears to cause it. This is interesting, if we follow for a moment the path of the pupillomotor reflex (Fig. 2).

The afferent fibres subserving this purpose leave the retina by the optic nerve and undergo a partial decussation at the chiasma, whence they pass to the anterior corpora quadrigemina. From here their path to the third nerve nucleus is not yet certain, and one observer (Majano[8]) has even suggested that the fibres have no cell station in the third nerve nucleus at all but pass directly as preganglionic fibres to the ciliary ganglion and thence to the sphincter iridis. The path of the impulses bringing about contraction of the pupil in association with accommodation-convergence must necessarily begin in the cortex (since this is a willed movement, synkinetic with convergence) and go on to the third nerve nucleus. It would thus appear that, distal to this nucleus, the pathways for iris contraction in response to light and to accommodation-convergence are identical, and this is shown experimentally by the fact that lesions of the third nerve trunk never cause an Argyll Robertson pupil reaction. Hence the site of the lesion must be on the afferent side of this nucleus, and the most likely one seems to be in the neighbourhood of the aqueduct, where fibres passing from the corpora quadrigemina to the third nerve nucleus may be caught before they enter the latter. Moreover, the accommodation fibres are sufficiently far removed from this neighbourhood not to be affected.

The special ability of syphilis to produce the lesion is to be attributed to the peculiar affection of the syphilitic toxin for the terminal aborisations of afferent nerves, the toxin spreading from the aqueduct into the subependymal tissues. The localisation of the lesion to this part of the brain may also serve to explain the myosis which is so frequently present, since it is probable that fibres carrying inhibitory impulses from the cortex to the sphincter iridis pass through the peri-aqueductal tissue, and so are affected by the toxin diffusing into this tissue.

In the interest of brevity I have made these remarks rather didactic. The localisation of the lesion producing the Argyll Robertson pupil is not yet by any means certain, and there are still several theories, but the one I have just given seems to be the most logical and to fit in best with observed clinical and pathological data and so to be worthy of notice, even in a general lecture.

It seems possible for an Argyll Robertson pupil to develop apart from any other manifestation of organic disease. I have seen one or two myself, and the cases have been carefully annotated and described by Foster Moore [9] and by Gordon Holmes.[10] The principal characteristics are that the affected pupil is usually larger than normal and does not contract to any form of light stimulus, the contraction to convergence being slow and relaxation also slow, usually taking 8 to 10 seconds, and in some cases as long as 90 seconds. Only one eye is involved as a rule and there is no sign of syphilis either serologically or clinically. In Foster Moore's cases, which number 15, there was no constitutional disease, nervous or otherwise, but in Gordon Holmes's 54 cases there were disturbances of some of the other reflexes in 19—e.g., the knee- and ankle-jerks might be absent. These cases are important and, judging by the numbers reported, are commoner than one would think. It does not do, however, to assume that a patient belongs to this category until syphilis has been definitely disproved.

This was brought home rather forcibly to me by a patient with an apparent Argyll Robertson pupil referred by a physician who expressly stated that there was nothing in the history to support the diagnosis of syphilis. She came after I had read the articles to which I have just alluded, and seemed to be a clear case of the condition. Vision in the eye with the Argyll Robertson pupil could not be improved beyond 6/12, though the other was normal, but this could be accounted for by the presence of a small area of pigmentary disturbance in the macular region of the retina. With the non-luetic hypothesis still in my mind, I inquired whether she had ever looked at an eclipse of the sun, since this might produce the pigmentary disturbance. I was rewarded by the assurance that she had done so when abroad a few years ago, and that while looking she had kept the left eye closed.

The case seemed a clear one, but to be on the safe side I thought it as well to have a Wassermann done—which, I need hardly add, was positive.

B. COLI MENINGITIS IN THE NEW-BORN

By John Gibbens, M.B. Camb., M.R.C.P. Lond.

CHIEF ASSISTANT IN CHARGE OF INFANTS, QUEEN CHARLOTTE'S HOSPITAL, MARYLEBONE; CHIEF ASSISTANT TO CHILDREN, ST. THOMAS'S HOSPITAL

In post-mortem examinations on new-born infants during the last year or so at Queen Charlotte's Hospital, three cases of meningitis due to the *Bacillus coli* have been seen. In one only of these was the diagnosis made during life; the other two were thought to be cases of intracranial hæmorrhage.

Cruickshank [1] believed that in many cases, possibly the majority, there is post-mortem invasion of the tissues by the organism: "one hesitates to attribute to coliform organisms a pathogenic rôle, but there are some cases in which they may be the causal organism." In one of my cases *B. coli* was recovered in pure culture from purulent cerebro-spinal fluid during life; in the other two cases post-mortem examinations were made shortly after death, and the organism was not only cultured, but found in direct smears of the pus. It seems likely that these three cases, at any rate, are true cases of *B. coli* meningitis.

CASE RECORDS

Case 1.—Girl born on April 10th, 1931, four weeks prematurely; the first baby of an apparently healthy mother. Normal labour; the child seemed perfectly well immediately after birth, took the breast well, and cried lustily. Puerperium entirely normal.

April 14th (fourth day): moderate amount of bright red blood passed per rectum during the night; 12 c.cm. of mother's whole blood injected into the child's buttocks, after which there was no more melæna.

April 17th (seventh day): mild fever, refusal to take the breast, and two loose green dyspeptic stools. Considerable œdema of the lower limbs (pitting on pressure) and of the scrotum, but no œdema of the back of the trunk, head, or arms. Nothing abnormal found in the abdomen or chest. Colour good. No abnormal physical signs in the central nervous system; fontanelle not tense. Cord normal. Skin normal. The baby did not seem ill.

April 18th (eighth day): temperature of 102·6° F. A catheter specimen of the urine showed no pus, but large numbers of Gram-negative bacilli; on culture a thick growth of coliform bacilli was obtained.

April 20th (tenth day): still passing green stools and developing sore buttocks. Œdema of lower limbs unchanged, but now has a puffy face.

April 24th (fourteenth day): œdema much the same, but hands and feet now definitely in a tetanic position. Chvostek and Trousseau's sign negative. Fontanelle apparently quite normal. No rigidity or paralysis and no squint. Nothing abnormal was found in the heart, lungs, or abdomen. Urine: no albumin and no pus.

At this point the case closely resembled those recently described by Shannon [2] under the title of Tetany, General Œdema, and Cerebral Compression in the New-born (see below), and so the child was ordered calcium chloride grs. 5 twice daily. In view of the absence of nervous signs apart from the tetany and apparently a normal fontanelle, no lumbar puncture was done.

April 25th (fifteenth day): the child had four fits in which she made "a curious cooing noise," screwed up the left eye and left angle of the mouth; this lasted about 15 seconds then ceased abruptly.

April 26th (sixteenth day): three more fits, as before. Urine: no pus.

April 27th (seventeenth day): four fits, as before. There was now more œdema of the eyelids, but no increase in œdema of the legs. The hands and feet were now in an extreme tetanic position. All reflexes increased; bilateral extensor response very marked. No increase in tension of the fontanelle. No squint or nystagmus. No stiff neck. No fever. No disturbance of respiratory rhythm—in other words, Shannon's complete clinical picture. Accordingly calcium-Sandoz (1·0 c.cm.) was injected intramuscularly and 0·25 c.cm. of parathormone subcutaneously.

April 28th (eighteenth day): condition of the child hanged. Urine: no albumin or pus. Considerable of weight and pallor. Slight increase in tension of the tanelle. Lumbar puncture in three places was successful.
April 29th (nineteenth day): death.

Post-mortem.—The hands and feet of the child were ll held in an extreme tetanic position, the most rked I ever remember to have seen. The brain s covered with a thick green layer of pus, almost e wash-leather. The pus was thickest at the base d at the tip of the temporal lobes; apparently pus had spread upwards from the base towards vertex. The pus was so thick over the spinal rd that obviously no fluid would have passed rough the needle on lumbar puncture. The right ddle ear was also full of pus, but the left middle was free from infection.

The heart, lungs, pericardium, and pleura were all normal the naked eye; no thymic enlargement. The liver and een were slightly enlarged; nothing abnormal was seen section. The kidneys, ureter, and bladder appeared lthy. No microscopical changes were found in the roid or parathyroid glands.

Direct smears of the pus from the meninges and ht middle ear showed *B. coli*, and on culture an nost pure growth of this organism was obtained.

Case 2.—A full-term female child, born after a ficult labour with forceps. White asphyxia mediately after delivery, which disappeared after hot bath and an injection of 1 c.cm. of coramine ramuscularly. For the first 36 hours of life no normal symptoms were noted except that the by was rather drowsy, but next day there were riods in which the baby was restless and crying ntinuously alternately with periods of somnolence. e baby took the breast with difficulty.

On examination there was slight stiffness of the neck d the mouth was set in a straight line suggesting an early as sardonicus. Fontanelle: normal tension. Pupils all; occasionally nystagmoid jerks. Kernig's sign gative; Chvostek sign negative. No abnormal physical ns were found in the heart, lungs, or abdominal organs. ine: no albumin or sugar; nothing abnormal micro- pically. Cord apparently healthy. Mild icterus onatorum.

The diagnosis was intracranial hæmorrhage following olonged labour with forceps and the treatment was solute rest with small doses of chloral.

The next day, the fourth day of life, the condition of baby was much the same, except that now there was ght irregularity of the heart—occasional bursts of tachy- rdia, followed by a succession of beats at the normal rate. undice slightly increased. The respirations were celerated and although no definite Cheyne-Stokes respira- ns were seen, they tended to be irregularly grouped. e fontanelle was now certainly a little tense, so a lumbar ncture was performed, and to my great surprise about c.cm. of thick pus was withdrawn after gentle aspiration th a syringe. From this pus *B. coli* was obtained in pure lture. Half an hour later the child had a general nvulsion and died.

At the *post-mortem examination*, 12 hours after ath, the brain findings were identical with those Case 1. Pus was present in the left middle ear, t in the right; a pure culture of *B. coli* was grown om this pus.

Pharynx, nasopharynx, and tonsils microscopically rmal; no ulcerative lesion of the mouth. Cord: no lence of inflammation. No ulcerative lesions were seen the stomach, duodenum, small or large intestine. Slight largement of the liver and spleen, microscopically early tty degeneration. The kidneys appeared normal to the ked eye.

Case 3.—Born on Sept. 10th, 1931, weighing lb. 9 oz. The mother had had a myomectomy rformed at Chelsea Hospital nine years previously, d when seen in the antenatal department at Queen Charlotte's on April 4th more fibroids were found. A note on August 10th says that the head could be pushed in well; per vaginam no obstruction, but fibroids tender on palpation.

She was admitted for induction, and pitocin (two units hourly for six doses) was given on August 31st, but since no pains came on during the following five days bougie induction was begun on Sept. 5th. During Sept. 8th and 9th, pains were very slight and little advance was made by Sept. 10th, so finally forceps were applied and the baby was delivered without any difficulty.

Immediately after birth the baby seemed quite normal, but on the third day the temperature rose to 101° F. On examination it was noticed that the child seemed abnormally limp and toneless and there was a peculiar fixity of gaze, but no rigidity or paralysis, and the fontanelle was not tense. The respirations were normal, and no abnormal physical signs were found in the abdomen, heart, or lungs. Mouth quite moist. Lumbar punctured in three places without success. Chloral was given, and the child kept absolutely quiet. Next day the fixity of stare was more marked, the child was refusing the breast, and there was now definite head retraction; the fontanelle was not tense. Death occurred a few hours later.

Post-mortem.—Changes in the brain identical with those in the other two cases. No pus in the middle ears, but pus in both pleural cavities. Macroscopically the heart, lungs, and abdominal organs appeared normal. Direct smears of the pus from the pleura and meninges showed *B. coli*, and this organism was obtained in almost pure culture.

DISCUSSION

Cases of *B. coli* meningitis have long been known. In 1895 Scherer [3] gave an excellent description of three infants, almost exactly the counterpart of Cases 2 and 3 described above. The condition is, however, said to be comparatively rare, and in 1926 Neal [4] could only collect 42 cases. The point of greatest interest is the source of the infection. Scherer [3] observed that his cases all occurred at a time when the hospital was overcrowded and thought that the Eustachian tube might have been infected with contaminated bath water; an otitis media resulted and a meningitis followed by direct extension. Such a theory would not fit in with our cases in which overcrowding and contaminated bath-water can be absolutely excluded. This primary infection of the middle ear with secondary invasion of the meninges is an attractive hypothesis and would certainly fit in with the clinical picture of Cases 1 and 2, but it is difficult to say whether this infection takes place antenatally, intranatally, or postnatally. Aschoff [5] has shown that passage of liquor amnii up the Eustachian tubes during efforts at premature respiration is fairly common, and that antenatal or intranatal infection can occur seems to be proved by the case reported by Hinsdale,[6] in which after expulsion of the placenta a large quantity of pus came away from the uterus. The baby subsequently died of *B. coli* meningitis. In a case of Barron's [7] it was highly probable that the infection had been conveyed by a finger introduced into the mouth of the infant during labour.

In other cases, the meningitis is apparently part of a generalised *B. coli* sepsis; in some apparently pus and *B. coli* are found in the urine, in others *B. coli* abscesses in the subcutaneous tissues. Case 1 must be regarded as one of these, the melæna on the fourth day being probably the first evidence of sepsis. This case presented considerable difficulty in view of the close similarity to tetany. At this time I had not read Koplik's excellent description of meningitis in the new-born [8] where it is stated that "the most frequent diagnosis apt to be ventured in a meningitis is tetany," but that tetany is even rarer than meningitis. Shannon's description of Tetany, General Œdema, and Cerebral Compression in the New-born[2] seemed to fit the picture perfectly. In these cases carpopedal spasms, extreme irritability, and sensitiveness to light and sound, increased reflexes and a positive Chvostek's sign were found; also œdema of the extremities and to a less extent of the trunk; and the sign of cerebral compression consisted in (1) periods of depression almost amounting to unconsciousness, (2) a slow pulse, and (3) cyanosis.

In two at least of Shannon's cases there was a history very suggestive of birth trauma, and post-mortem examination in one case showed severe œdema of the brain. On treatment with calcium, parathormone, and ergosterol, some of his cases recovered. Looking back on Case 1, it is clear that lumbar puncture should be performed in all new-born infants showing symptoms of disease in the central nervous system. Only by lumbar puncture can the true diagnosis be established.

Several lessons were learnt from these three cases: firstly, that pressure signs are often absent in meningitis and bulging of the fontanelle occurs late if at all. The anatomical conditions within the skull, the immaturity and lack of functional differentiation of the brain at this early age, the rapidity with which pathological changes in the nervous system of new-born infants takes place, the considerable degree of expansion of the brain that may take place within the skull before there is any evidence of increased intracranial pressure—these all account for the fact that cerebral diseases in the new-born have quite a different symptomatology from those in the adult. Instead of localising cortical or meningeal signs, we are dealing with symptoms and signs which are mainly due to irritation or paralysis of the medulla. In some of the cases reported there have been no symptoms whatever beyond trifling fever and the meningitis has been discovered only post mortem. In doubtful cases lumbar puncture should always be done to settle the diagnosis, although it is futile from the point of view of treatment, as no case has ever yet recovered. The longest duration of the disease I have found reported was in Noeggerath's case.[9] This child, born after normal labour, had convulsions on the eleventh day and œdema and petechiæ of the hands and feet on the seventeenth day. There was also a facies resembling tetanus neonatorum, increased nervous excitability, twitchings on the slightest percussion of the skin, a positive Trousseau's sign (although a negative Babinski and Chvostek's sign), and irregular intermittent fever. In the eighth week there was a bilateral ear discharge. The fontanelle was slack and never bulged throughout the whole illness. Death occurred three months after birth, and post mortem *B. coli* meningitis with an internal pyocephalus was found.

A FURTHER CASE

The following case may be added, in view of the frank cerebral symptoms, although definite evidence of meningitis was not found.

On Nov. 7th a boy was seen at Queen Charlotte's Isolation Hospital, at the age of 4½ weeks. Birth weight: 8 lb. 11 oz. The weight had dropped to 7 lb. 14 oz. on the third day of life, and after this there was a very slow gain, so that the birth weight was not regained till the thirtieth day. During this time there were no symptoms of any kind. Fed on an ordinary milk mixture. On Nov. 7th, the thirty-third day of life, the temperature suddenly rose in the morning to 106·5° F., the infant developed a greyish pallor, the respirations became extremely rapid, and the pulse-rate uncountable.

Seen at 5 P.M. on Nov. 7th, the temperature had dropped to 103°. The baby looked extremely ill, with a toxic appearance—big staring deeply-sunken eyes, and acute dehydration. The mouth and tongue were very dry, and the fontanelle slightly sunken. The respirations were very rapid and shallow, and the pulse could only just be felt. No abnormal physical signs were found in the lungs or heart, and none in the abdomen. No rigidity of the neck and no squint. No specimen of the urine was available.

Diagnosis.—? pyelitis. A catheter specimen of the urine was ordered, and water was given in large amounts by the mouth, also subcutaneously.

Nov. 8th.—At 5.30 A.M. the baby began to have left-sided convulsions. Seen at 10 A.M., the baby was semi-conscious, having rhythmic clonic twitchings about one a second of the left arm and leg and of the left side of the face and tongue. The right ear was pouring stinking pus; the left drum was injected but not bulging. The fontanelle was a little tense. Pupils equal size, reacting well to light; no squint; no stiff neck; Kernig's sign negative; no rigidity of the arms or legs. There was now much less dehydration and the mouth and tongue were moist. Respirations and pulse-rate still very rapid. No abnormal physical signs in the abdomen, chest, or throat. Stools normal.

Diagnosis.—Meningitis secondary to otitis media.

During the day, the following investigations were made: (1) Pus from the right ear swabbed; mixed growth of *B. coli* and *B. proteus* obtained. (2) Lumbar puncture; 0·5 c.cm. of clear fluid under normal pressure removed. Sterile; no increase of cells or protein. (3) 4 c.cm. of blood aspirated from the superior longitudinal sinus for blood culture; pure growth of *B. coli* obtained. (4) Urine cultured; mixed growth of *B. coli* and *B. proteus*. At 10 P.M. he was very much better and now perfectly conscious, but getting dehydrated again. Took water greedily from the bottle. Pus still pouring from right ear; left drum unaltered. Respirations now 36 per minute; no Cheyne-Stokes respiration. No twitchings since lumbar puncture at 10 A.M. Treatment: all food stopped and water given ad lib.; chloral and bromide; H_2O_2 to the right ear.

Nov. 9th.—5 P.M. Temperature 98·6°. Irritable when roused, but otherwise rather drowsy. No stiff neck. ? slight rigidity of the legs; accentuated knee-jerks and bilateral extensor response. A few *right-sided* twitchings were noticed in the morning; none present at 5 P.M. Fontanelle normal. Abdomen, chest, and throat normal; mouth now quite moist. Normal stools. Treatment: 15 per cent. dextrimaltose solution ad lib.; seven feeds of 1 oz. of ordinary milk mixture. Potassium citrate and sodium bicarbonate, grs. 20 of each, four-hourly.

Nov. 10th.—Very much better. No physical signs whatever. Seven feeds of 2½ oz. taken well. Urine: no pus.

Nov. 12th.—Weight: 8 lb. 3 oz. During six days, loss of weight has been 11 oz.

Nov. 16th.—Still rather pale, but has gained 6 oz. in four days; taking all feeds well—six feeds of 4½ oz.; normal stools.

This child was kept in hospital for six to seven weeks more, during which time there was never any recurrence of the cerebral symptoms. An acute attack of fever occurred in December, when the urine was found to contain pus and *B. coli*; this responded rapidly to the ordinary alkaline treatment. Finally, he was discharged well, without any nervous or urinary signs whatever; no ear discharge.

Diagnosis.—*B. coli* septicæmia with cerebral symptoms, pyelitis, otitis media.

I should like to thank Dr. R. M. Fry and Dr. Elizabeth Cooper, pathologists at Queen Charlotte's Isolation Hospital, Goldhawk-road, by whom most of the pathological work was done; and Dr. Eric Pritchard for permission to publish the cases.

PAPWORTH VILLAGE SETTLEMENT: NEW HOSPITAL. A new hospital for men is to be built at the *Papworth Village Settlement for Men* with gifts of £20,000 from the trustees of the late Mr. Bernhard Baron and £2500 from the joint war finance committee of the British Red Cross Society. The building, which is to be "constructed by Papworth's own industries," is to be named "The Bernhard Baron Memorial Hospital."

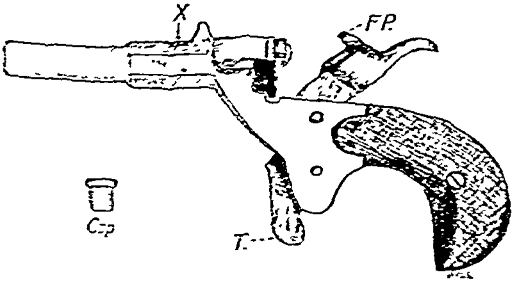
TETANUS CAUSED BY TOY PISTOL WOUNDS

By GWENDOLINE SMITH, M.D. LOND., F.R.C.S. ENG.
SURGICAL REGISTRAR, ROYAL FREE HOSPITAL, LONDON

THE low rate of incidence of tetanus at the present time is undoubtedly due to the widespread prophylactic administration of antitetanic serum (A.T.S.), and the following cases are reported in order to indicate an unusual type of injury in which it is essential that serum should be given. In each case the wound was the result of playing with a toy pistol, part of the charge entering the hand. These pistols are often of foreign manufacture and are badly made. Considerable force is required to pull the trigger, which often jams, and it is probable that the pistol is held with two hands in order to steady. It is obvious that in this case one hand would be placed on the barrel and the metacarpal region of the hand would be just over the hole from which the charge escapes (X). Three of the four cases were fatal, the deaths all occurring in London in the first four months of 1932. These three deaths seem to us important enough to warrant a brief record of the cases.

CASE 1.—A boy, aged 18 years, occupation "domestic" (exact nature unknown), was admitted to the County Hospital, York, on May 10th, 1928.

History.—On May 3rd the patient was playing with a toy pistol and received a wound in the right hand. The charge entered the palmar aspect of the metacarpal region, and emerged on the dorsum. He was treated in the casualty department of the hospital, some fragments were removed from the wound, which was sutured and dressed. No A.T.S. was given at the time of the injury. The wound appeared to be progressing satisfactorily during the next few days, but on May 8th the boy complained of backache and general malaise, and on May 9th had more definite stiffness of the back.



F.P. = Firing pin. T. = Trigger. X. = Where charge escapes.

On admission, on May 10th, there was definite trismus and rigidity of legs and arms, but no spasms. The wound of the hand was mildly infected, but there was no cellulitis or pus present and no suggestion of gas gangrene. Treatment with A.T.S. was commenced at once, and there was definite improvement in the symptoms until May 13th, when he was more rigid and had a severe serum rash. He remained in a serious condition for the next five days, and on May 18th there was marked opisthotonus and risus sardonicus. After this day there was definite improvement again, and on May 27th there was no stiffness, he could eat solid food and felt well. He was discharged cured on June 20th.

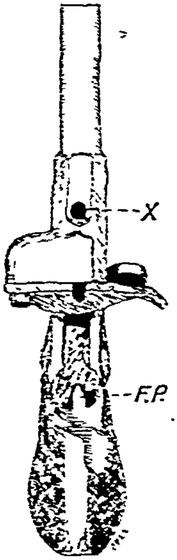
Treatment.—On admission (May 10th) 2000 units of A.T.S. were given by intramuscular injection, 20,000 units intravenously, and 27,000 units intrathecally; and on May 11th and 12th 10,000 units intravenously with 10,000 units intrathecally. Intravenous injections were given daily until May 18th, when the symptoms were worse and [illegible] units were given intrathecally. Intravenous injections of 10,000 units daily were continued until May 23rd, and for two more days 10,000 units were given by intramuscular injection. In all, 252,000 units of concentrated A.T.S. were administered. The usual symptomatic treatment was carried out; the wound was not opened up, but healed gradually with antiseptic dressings.

CASE 2.—A butcher's assistant, aged 17 years, was admitted to the Royal Free Hospital, London, on April 7th, 1932.

History.—On April 1st, whilst the boy was playing with a toy pistol, which was jammed, the charge from the cartridge entered his left hand between the thumb and first finger. He was treated in the casualty department, the wound being explored, cleansed, and stitched. The following day, as the wound was inflamed, the stitches were removed and fomentations applied. These were continued until he was admitted with tetanus on April 7th. The earliest symptom was backache on April 6th.

On admission, on April 7th, he had definite trismus and generalised stiffness. The wound was deep in the first metacarpal space, and although the tissues were sodden and infected there was no gas gangrene. Antitetanic serum was given, but the symptoms became rapidly worse. After about 12 hours the spasms became almost continuous and the boy died on April 8th, less than 24 hours after admission, and only 40 hours after the onset of symptoms.

Treatment.—On admission the patient was given 20,000 units of A.T.S. by intravenous injection, and 20,000 units by intrathecal injection. In addition, 41,000 units were given by intramuscular injection, making a total dose of 81,000 units of concentrated serum, and for some hours before death chloroform was required for the spasms.



After death the parts surrounding the wound were excised and dissected; the muscles were soft and pulpy, and no foreign material could be detected. Films showed scanty pus cells and a small number of cocci and Gram-positive non-sporing bacilli. Blank cartridges of the same batch as those used by the patient could not be obtained for examination. From a box bought in the same district six cartridges were picked to pieces, the small white circular padding cut up, and the fragments cultured in meat infusion tubes under anaerobic conditions. The cultures remained sterile, with the exception of a few aerobically growing cocci.

The two following cases I did not see, but was told about them by the coroner after the inquest on Case 2.

CASE 3.—A man of 26, a sewerman, was admitted to the Royal Northern Hospital, London, on Dec. 31st, 1931.

History.—On Dec. 24th he bought a toy pistol, and when firing it at home injured his right hand at the base of his first finger. He was treated in the casualty department of the Royal Northern Hospital until Dec. 31st, when he was admitted with lock-jaw. Large doses of antitetanic serum were given, but he died on Jan. 2nd, 1932, about 48 hours after admission.

CASE 4.—A man, aged 50 years, occupation furrier, was admitted to St. Mary's Hospital, London, on March 5th, 1932.

History.—On Feb. 27th he bought a toy pistol, and whilst trying it in the shop received an injury in the left hand at the base of the first finger. He was treated immediately by a chemist, who also dressed the wound for the next four days. On March 4th he complained of a sore-throat. On March 5th he had stiffness of the jaw and was admitted to hospital. He died on March 7th, 44 hours after admission, about 50 hours after the onset of definite symptoms.

Treatment.—On the day of admission the patient was given 5000 units of A.T.S. intramuscularly, 75,000 units intravenously, and 20,000 units by intrathecal injection.

On March 6th 100,000 units were given intravenously—a total of 200,000 units.

The coroner kindly supplied us with a blank cartridge similar to that bought by this patient. It was a different make from those previously tested, being marked with an "E," and the wadding appeared to be rather more bulky. Fragments were distributed into two meat infusion tubes and cultured anaerobically; after 48 hours both showed a cloudy growth, accompanied by a putrefying smell and free gas formation in the medium. The organisms were small, rather slender, Gram-positive bacilli, with occasional longer filamentous forms, and numerous sporing forms containing oval, subterminal spores distending the bacillus. Nothing suggestive of *B. welchii*, and no end-sporing bacilli were seen. These cultures in amounts of 0·1–0·5 c.cm. were injected subcutaneously into mice and guinea-pigs, and were tolerated without apparent ill-effects.

Further attempts to isolate the tetanus bacillus, if it should be present in these primary cultures in small numbers, were carried out by successive platings from the filamentous growing edge and the water of condensation, but without success.

Cultures from the wadding of this cartridge thus yielded bacillus sporogenes only. In view of the difficulty of isolating the tetanus bacillus from mixed company, this failure does not negative the possibility of the presence of tetanus spores, and the demonstration of other anaerobic bacteria indicates the wadding as the probable source of infection.

COMMENT

The similarity of these cases is quite evident. In each case there was a deep wound of the hand, and it is interesting to note that this was the site of injury traditionally believed to be the cause of lockjaw. Similar treatment was carried out in casualty departments and by the chemist in Case 4, and the wound became mildly infected or appeared to be superficially satisfactory. In no case was there evidence of gas gangrene nor of frank suppuration requiring incision. This type of penetrating wound with mild secondary infection provides almost the optimum media for the growth of anaerobic organisms if such are present, and the primary suture of the wound renders the conditions even more favourable. It should be noted that no prophylactic A.T.S. was given in any of the cases.

The symptoms of tetanus developed in each case between the fifth and seventh day following the injury. Such a short incubation period is well recognised as one of the features of the most severe cases of tetanus. The time elapsing between the initial symptoms and the appearance of definite signs of tetanus was longest in Case 1, where the prodromal backache commenced two days before admission. In the fatal cases the symptoms developed within 18 hours. This rapid development of symptoms has been shown to be an index of the severity of the infection in a series of cases recently reported from an agricultural area, where the symptoms in all the fatal cases developed in two days or less.[1] The treatment adopted for the fully developed disease varied only in the amount of serum which was given. The initial dose given in Case 1, which recovered, was smaller than in any of the fatal cases, although the symptoms on admission were as severe as those of Case 2, who died within 24 hours. The very large dose given to Case 4 did not succeed in preventing a fatal issue. It is, however, impossible to tell at the beginning which cases will prove fatal, and therefore large doses of serum should be given immediately. A very rapid development of symptoms would seem to indicate an unfavourable prognosis.

AMERICAN EXPERIENCE

Tetanus resulting from toy pistol and blank cartridge wounds does not seem to have received much notice in England, but it was well recognised in the United States, where it was known as Fourth-of-July tetanus, owing to the large number of cases following the Independence Day celebrations. In 1903, in spite of official warnings of the danger of tetanus from these wounds, over 400 deaths were reported.[2] The infection in these patients was extremely virulent, the incubation period being only four to five days, and death occurring within 72 hours. In the majority of the cases the wounds were in the hands. In order to reduce the heavy mortality in future years, the prevention of the sale of toy pistols and blank cartridges was recommended, and physicians were advised not to dress the wound without removing the cartridge wad, and also to give a prophylactic dose of A.T.S. The measures taken were evidently successful, for only three deaths were reported after the Independence Day celebrations in 1914.[3]

In an analysis of 813 cases of tetanus occurring in a New Orleans Hospital between 1906 and 1930, Graves [4] reported 24 cases due to blank cartridge wounds, occurring mainly after celebration days—the mortality being 83·3 per cent.

ORIGIN OF INFECTION

It is interesting to discuss the possible origin of the infection in this type of tetanus. The bacilli must either enter the wound in that part of the charge which penetrates the deeper tissues, or be carried in from the skin, or be introduced at a later date. The last suggestion seems the least likely in the cases here reported. The diverse occupations of the patients could scarcely account for this type of infection, especially as the wounds appeared to heal satisfactorily on the surface. Nor is it probable that the infection was carried in from the skin at the time of the accident, though this is suggested as a possible factor in some of the Fourth-of-July cases.

The wad which keeps the powder in the end of the cartridge is said to be made of coarse horse-hair felt, which might convey spores. This wad was investigated in connexion with Cases 2 and 4, but no tetanus bacilli or spores were isolated. Following the 1903 fatalities, a large number of blank cartridges were investigated.[5] In no case was the tetanus bacillus isolated by direct culture, but in one animal series the wad, together with a loop of an aerobic culture, was inoculated into rats, and 9 out of 12 animals died in convulsions. The conclusions reached were that there was abundant evidence from clinical observations that the wads contained tetanus bacilli, although no absolute bacteriological proof could be obtained.

It is evident that tetanus bacilli or spores are present in these toy pistol wounds, and although the number of cases is small, fatalities can be avoided if the importance of a prophylactic dose of serum is realised, and if in addition the wound is excised or laid open instead of being sutured.

Dr. C. Weatherall, bacteriologist to the Royal Free Hospital, has investigated the cartridge wads, and I am indebted to her for the bacteriological reports. I have to thank Mr. F. D. Saner and Mr. R. M. Handfield-Jones for permitting me to use the notes of Cases 3 and 4, which I did not see; Mr. C. A. Joll for permission to publish Case 2; Mr. G. W. Gostling for allowing me to treat and report Case 1, and Dr. Bentley Purchase, coroner for St. Pancras, for giving me much helpful information.

Dr. P. F. L. Simon has kindly made the illustrations of the toy pistol.

STREPTOCOCCAL SEPTICÆMIA MPLICATING EPIDEMIC INFLUENZA

RONALD E. SMITH, M.B. CAMB., M.R.C.P. LOND.
ICAL OFFICER OF RUGBY SCHOOL, AND ASSISTANT PHYSICIAN TO THE HOSPITAL OF ST. CROSS, RUGBY

N a recent symposium in the *Guy's Hospital* orts[1] the clinical features of streptococcal ticæmia were discussed at some length. The nparative rarity of the disease is evidenced by being able to find only 21 examples admitted Guy's *Hospital between 1921 and 1930. The two* es to be described hereunder both occurred during influenza epidemic. The second case was of the minant type and similar to Case 2 in Part I. of paper referred to above.

DESCRIPTION OF CASES

ASE 1.—A lean, sallow but alert boy of 15½, se mother had died of streptococcal septicæmia owing labour, had been seen by Dr. John Parkinson January, 1931, for a faint systolic murmur heard his apex-beat. Dr. Parkinson thought, on radio- ical evidence, that his heart was slightly enlarged, l ordered moderate exercise. The patient played ket without fatigue or dyspnœa. Of some 20 boys is house who had not previously had chicken-pox had been the only one to escape infection during epidemic in the previous term. His tonsils and noids were removed in December, 1925, and there e no tonsillar remnants.

e contracted epidemic influenza on Feb. 1st, 1932, h was probably the eighth or ninth day after contact. had a slight frontal headache and a mild sore-throat. ch was studded with small raised lymphoid nodules. following day he had a very sore-throat and slight derness over his left frontal region with headache, eved by inhalations. These complaints quickly sub- d, but the tenderness reappeared over the left frontal on on Feb. 9th, to disappear next day. On Feb. 11th had a folliculitis on the posterior pharyngeal wall, and adenoids, which could be seen projecting below the la, also showed purulent follicles. Next day there was enormous boggy mass on the right, obliterating the right sillar fossa and extending as an œdematous swelling l over to the left side of the soft palate. This subsided three days, but a precisely similar swelling appeared on right side. There was a large diffuse mass of glands ind the left ear.

e was gravely ill, and there was much difficulty in feeding . He had the mildest delirium on the night of the 17th, ncident with his fall of temperature or "crisis." On 16th he vomited practically everything given him and ted to have diarrhœa, having five copious very fluid k brown stools on the 17th, and four the following day. m these *Bacillus coli communis* and *Streptococcus brevis* were grown. A blood count (17th) showed 12,500 white d-cells (polymorphs 86 per cent., lymphocytes 5·5 per ., and mononuclears 8·5 per cent.). On Feb. 18th a ll patch of purpuric spots appeared over the anterior l of his right axilla, and there were numerous scattered echiæ over his trunk and arms, and a few on his legs. od culture, which was done that evening, was negative. L. G. Parsons saw him with me at this stage and agreed t he had a blood-stream infection with streptococci, and e a hopeful prognosis. He felt the spleen, which I was able to feel at any time. From Feb. 16th to 21st the had albuminuria, but two microscopic examinations ed to reveal casts or red blood-cells. On Feb. 19th the spots were more numerous and larger, situated mostly on the back and trunk, and a fresh crop appeared the following day, but from then onwards they rapidly faded, leaving definite staining.

At 7.30 P.M. on Feb. 21st he coughed up about 2 drachms of ropy rose-coloured sputum, which was odourless and tasteless. The bacteriological report on this was: direct examination showed pus cells, streptococci, gram-negative bacilli and filaments; gram-negative cocci and fusiform bacilli. The predominant organism in culture was the hæmolytic streptococcus. *Micrococcus catarrhalis* was also grown. No *B. pfeifferi* were seen. Although the expectoration of this material did not immediately relieve his throat symptoms, yet from that time the swelling and glands quickly subsided, until by Feb. 24th the glands were normal. On Feb. 27th he was up for 20 minutes without undue fatigue, and by March 4th he was walking up to three miles a day, and went home to convalesce. During the illness his weight dropped from 102 lb. (Jan. 21st, 1932) to 85 lb. (March 3rd, 1932).

In this case of streptococcal fever the throat bore the brunt of the infection, and there seems no reasonable doubt that he had a quinsy which burst on Feb. 21st, but the succession of purpuric spots occurring synchronously with his diarrhœa, vomiting, and albuminuria, and possibly a splenic tumour, is strong confirmatory evidence that there was a blood-stream infection with streptococci.

CASE 2.—A robust, florid boy of 14½ had an early carditis in July, 1928, following tonsillitis, but made a complete recovery. Tonsillectomy was performed in February, 1929. His pulse-rate during convalescence from measles in March, 1931, averaged 72. On January 29th, 1932, he "felt rotten" all day but played what the other players called a magnificent game of hockey. That evening, when his temperature was found to be 100·4°, he was put to bed but had no symptoms except malaise and a very injected and slightly œdematous throat. He was considered to have epidemic influenza, having been exposed to it. The following day, when he had a temperature of 105°, a pulse-rate of 130, and a respiration-rate of 28, he still complained only of malaise, and he had no physical signs except a doubtful diminished air entry at the left base, and a thickly furred tongue and throat, and laboured respirations. His leucocyte count was 5000 per c.mm.

Lord Dawson saw him that evening (30th) and came to the conclusion that he had influenza with a streptococcal infection of the throat and possibly of the blood stream as well. Later that evening he vomited much bile-stained material, was incontinent of urine and fæces, and had the most explosive and copious diarrhœa on that and the following day. He was extremely restless and stuporose but not delirious. In view of his low blood count he was given intramuscularly that evening 20 c.cm. of antiscarlatinal serum, followed by 15 c.cm. the next day and 25 c.cm. on the following day. The accompanying table gives his daily blood counts.

On Jan. 31st the diarrhœa and mental derangement disappeared, and he recognised everybody from that time onwards. That day he had one diarrhœic stool. The fur on his tongue was disappearing, and the following day he had a smooth, lilac-coloured, moist tongue dotted with red papillæ. His throat was red and hæmorrhagic in places. On Jan. 31st and Feb. 1st and 2nd there was a trace of albumin in his urine, not measurable by Esbach's albuminometer. He was taking fluids and light nourishment well and was continent.

On Feb. 2nd, high-pitched bronchial breathing was heard over two separate areas the size of a florin, 1 inch from the apex of the right upper chest behind; there was also slight impairment at the right base. He had pain on deep breathing over the apex. That evening he became desperately ill, had acute meteorism, and was tender over the entire abdomen but especially over the right iliac fossa. The dullness at the right base was increasing. Blood culture (Feb. 3rd, when his temperature was 103°) gave a growth of *S. hæmolyticus*. The same organism was later grown from both pleural cavities. Next morning (3rd), when Lord Dawson saw him again, his abdominal condition had completely subsided but the dullness at the right base had increased and low-pitched bronchial breathing and absent tactile vocal fremitus were noted. He was needled, and some thin chlorine-coloured fluid was obtained which, on settling, gave a sediment of less than ½ inch in 3 inches of fluid.

From then onwards he held his own, except that his respiration-rate rose gradually to 44 on the 5th, when 15 ounces of fluid was removed from the right chest; this fluid was not appreciably thicker than before, but its removal eased his respiration slightly. His heart was displaced only ½ inch to the left. On Feb. 6th he was again seen by Lord Dawson, who detected a pleural friction rub in the sixth space in the left nipple line. A deep breath provoked pain over this spot. He was then extremely ill, but in view of the involvement of the left chest, and as his white blood-cell count was 23,000, it was decided to drain the right side. This Mr. B. L. Laver did under a local anæsthetic, the patient giving all the help possible by his willing coöperation, despite his grave condition. About 1½ pints of flaky pus drained away at the time of operation and during the night. The improvement after the operation was not marked, partly because the septicæmia continued and partly because of the presence of the effusion which was collecting on the opposite side, and perhaps partly because—despite the dexterity of the operator—the wound was not completely air-tight. The left pleura was needled but only a few *drachms of turbid fluid were obtained* and the needle gave the impression of underlying solid lung. It was therefore decided to try to make the wound air-tight, which was easily done by the introduction of a Tudor Edwards tube; the patient's breathing and condition quickly improved. However, at 2 A.M. on Feb. 8th he suddenly collapsed and died in a few minutes.

DISCUSSION

Ryle[1] lays stress on the four symptoms of diarrhœa; albuminuria with red cells and casts; a rapidly progressive anæmia; and a smooth, red, desquamated and sore tongue, as a diagnostic syndrome in blood-stream infections with hæmolytic streptococci, but points out that all are not invariably present. Both my cases had transient diarrhœa, but apart from that they had well-formed stools. Both had albuminuria, but one certainly had no red cells nor casts, nor probably did the other. Despite the fact that a hæmolytic streptococcus was grown from the blood of Case 2, yet his hæmoglobin was 95 per cent on the eighth day of his illness. Both had smooth, red, and desquamated tongues, although these were not subjectively sore. The tongue in Case 2 was usually a deep puce colour, corresponding to the colour of his lips and extremities, which was little influenced by oxygen intake.

What remains a most useful diagnostic sign is the mental acuteness of these sufferers, long since recognised in the puerperal cases. As Osler and McCrae[2] put it: "Certain clinical features separate the streptococcus from the staphylococcus infection, chiefly the absence of delirium, a rather abnormal mental acuteness, and the presence of a greater degree of anæmia." Apart from the initial stupor of Case 2, and the very mild delirium of Case 1 at a time when his temperature was dropping and he was considerably dehydrated owing to his throat condition, delirium was completely absent. In dealing with these very ill patients one cannot but be grateful to them for their willing coöperation.

Influenza and streptococcal septicæmia frequently occur together, and there is no doubt that the patient suffering from the dual infection requires special consideration and handling. It has long been known that influenza initially produces a leucopenia which may pave the way for the entry of the streptococcus into the blood stream. What this may do in a short time is graphically shown in Case 2 (Part I.) of our paper,[1] and those who recall cases during the pidemics of 1918–20 will probably remember ny similar instances. However unwise it may be draw conclusions from a single case, it seems ossible in Case 2 that the serum may have prevented ath in the early period of invasion. It has been stomary to look upon a moderately high tempera- re (104°–105°) in infection as a good prognostic gn, but Fig. 2 shows that, though it may give n indication of the quality of the resistance the ody is making, it bears no relation to the quantity, we accept the leucocytic response as a true index f resistance, as I believe we can. As has been shown efore, most cases of uncomplicated streptococcal pticæmia have a good polymorphonuclear leuco- tosis, and serum is not required, but where the efences of the body have been already hampered—hether by acute infections such as influenza or phoid, or by such chronic diseases as diabetes or ephritis—then serum has a place in therapy.

The reason for dealing with this point at length that previously I have tried to show the inefficacy antistreptococcal serum in septicæmia, and partly answer some recent criticisms made by A. H. G. urton and A. R. Balmain,[3] who insisted that anti- carlatinal serum benefited a case of broncho-pneu- onia with pericarditis complicating streptococcal pticæmia, and supported their plea for its employ- ent by Cadham's [4] figures: that 45 out of 56 cases f septicæmia (mostly streptococcal) recovered under rum therapy. Careful reading of this paper shows hat the method employed by Cadham was to give uman serum and 2–5 c.cm. of immune rabbit's erum on alternate days, and Cadham also remarks: 'The beneficial results occasionally obtained in psis following the use of scarlet fever antistrepto- occic serum touches the live question of the relation f the toxins from the various strains of streptococci o one another." Although Cadham's figures are riking, I have the impression that his cases were ot unselected, but as no details are given it is not ossible to be certain. Burton and Balmain also note Comber's [5] figures to show that antiscarlatinal rum gives good results in streptococcal septicæmia, ut they do not mention that all her cases were of carlet fever. There is no denying the good results f antiscarlatinal serum in scarlet fever cases, but see little reason for its use as a routine in uncom- licated streptococcal septicæmia, although the bsence of the leucocytic response may give the orrect indication for serum therapy in doubtful ases. But whether serum be given or not, success ill not be achieved if devoted nursing, hydro- herapy, the expectant treatment of metastatic bscesses, and as complete rest as possible are not llowed to play their part.

NEW THEATRE AT KESWICK HOSPITAL.—Sir John andles recently opened a new theatre which he has given Keswick cottage hospital at a cost of £8000. It is a emorial to the late Lady Randles, and is named after her.

PAYING PATIENTS AT CANTERBURY.—At the Kent d Canterbury Hospital a large temporary ward for ildren has been erected, and the accommodation s vacated is to be used for paying patients. The pening ceremony was performed by Lord Northbourne ntly.

Clinical and Laboratory Notes

A CASE OF NEPHROSIS

WITH A NOTE ON INFECTION AS A POSSIBLE CAUSE

BY HORACE EVANS, M.D., M.R.C.P. LOND.
SECOND ASSISTANT AND REGISTRAR TO THE MEDICAL UNIT, LONDON HOSPITAL

THE term nephrosis was originally suggested by Müller [1] to distinguish between degenerative and inflammatory changes in the kidney. Later it was applied by the clinician to differentiate a group of cases exhibiting certain special features—namely, intense albuminuria, gross œdema, low plasma proteins and high blood lipoids, and the absence of hæmaturia, hypertension, retinitis, and nitrogen retention. Such cases were placed in a definite group by Epstein,[2] Munk,[3] and Volhard and Fahr.[4] This dual definition has resulted in a very considerable confusion. The confusion has been increased by two other factors. From the pathological point of view, most examples of tubular degeneration show some evidence of inflammatory glomerular change, while from the clinical point of view many cases of true diffuse glomerulo-nephritis may show, over long periods of time, a clinical picture consistent with a diagnosis of nephrosis as based on the criteria quoted above. The situation has been further complicated by the necessity of distinguishing amyloid disease of the kidney and apportioning it a place in the classification of renal disease.

In spite of these difficulties the term has persisted. The reason for this persistence has been, not its pathological usefulness, which, owing to the varied character and ætiology of renal degenerations, has proved largely illusory, but its usefulness to the clinician to designate a group of cases recognised by him as a definite clinical entity. These cases, which had formerly been included among cases of diffuse glomerulo-nephritis under the headings sub-acute nephritis, chronic parenchymatous nephritis or hydræmic nephritis, urgently required separation and definition. This has now been achieved by the introduction of the term "nephrosis" or "lipoid nephrosis." A similar clinical picture arising in a patient suspected of amyloid disease may be designated "amyloid nephrosis." Though difficulties of differentiation in given cases between nephrosis and the nephrotic type of glomerulo-nephritis are bound to arise, they do not invalidate the use of the term. A careful watch for the occurrence of hæmaturia, hypertension, retinitis, and signs of deficient renal function will assist in the admittedly difficult differentiation.

Nephrosis as defined above is a relatively rare condition. The case here described is believed to be an example. It is considered worthy of recording because it has been carefully observed and because it may present some evidence concerning the unknown ætiology of the condition.

CASE RECORD

A married man, aged 49, was admitted to the London Hospital on April 17th, 1931. (No. 30567.)

Ten weeks previously he had had an attack of influenza; he had suddenly felt ill and tired, with a slight cough, headache, and fever, associated with profuse sweating. He remained in bed for ten days and did not return to work for a further period of ten days. After having been back at work for about three weeks he began to notice swelling of his legs towards the end of the day. This got worse during the next few days and spread up to his back. He saw his doctor who reported his urine to be "solid with albumin." At this time, apart from feeling a little tired, he complained of no symptoms other than the swelling. He had never noticed any change in the colour or quantity of his urine.

He had contracted syphilis thirty years ago and been treated with medicine. Nine months before admission he attended the Royal London Ophthalmic Hospital for failing vision. He was given seven injections of N.A.B. (novarsenobillon) at weekly intervals. Since 1924 he had suffered from frequent attacks of "nasal catarrh."

EXAMINATION AND INVESTIGATIONS

He was a well-developed man with slight pallor of the skin and mucous membranes. There was no puffiness of the face, but well-marked pitting œdema over the feet, legs, and to a lesser degree over the lumbar *region*. The heart was not enlarged. There was no vascular hypertrophy. Blood pressure 115/80. At no time during the whole course was any hypertension observed. A few scattered rhonchi were heard in both lungs. There was no ascites. The kidneys could not be felt. The pupils reacted to light somewhat sluggishly. Examination of the fundi oculi revealed old neuroretinitis shown by the presence of scattered areas of dust-like pigmentation in both retinæ. This was considered to be syphilitic in origin.

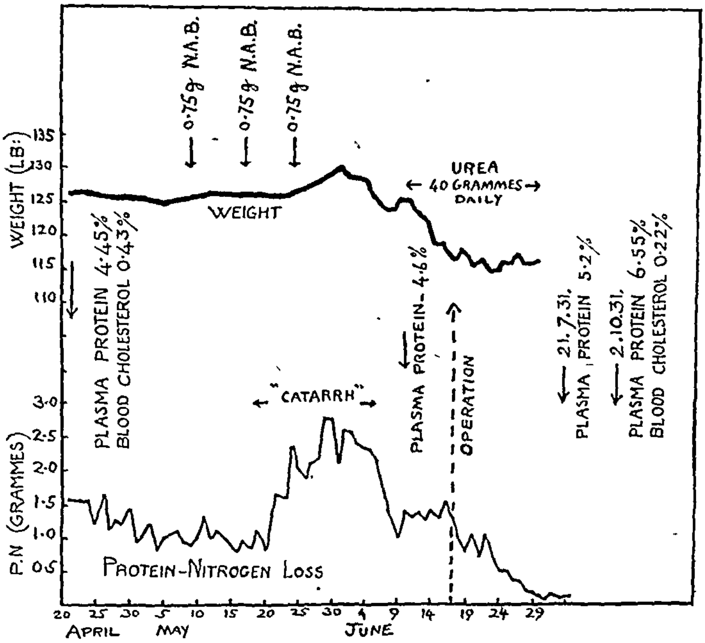

Chart to illustrate progress of case.

At this time investigations showed the following:—

Urine: S.G. 1022. Acid 2/3 volume of albumin. Daily volume 1000–1500 c.cm. Deposit, occasional leucocytes and red cells. Culture, streptococci.

Renal function: Blood-urea 0·022 per cent. 1st vol. 71 c.cm. 2nd vol. 69 c.cm. Phenolsulphophthalein 40 per cent., 20 per cent. Urea excretion, 0·84 per cent., 0·84 per cent. Standard clearance 83·20 per cent. of N., 81·90 per cent. of N.

Plasma protein, 4·45 per cent. Blood Wassermann reaction, positive. Blood cholesterol, 0·43 per cent.

Blood count: Red cells, 5,000,000; hæmoglobin, 70 per cent.; colour-index, 0·7; leucocytes, 11,200; polymorphs, 68·5 per cent.; eosinophils, 3·0 per cent.; small lymphocytes, 10·5 per cent.; large lymphocytes, 13·5 per cent.; large hyalines, 4·5 per cent.

COURSE OF ILLNESS

This case was observed in hospital for a period of nearly 14 weeks. As will be seen from the accompanying chart there was little change either in weight or in protein output during the first five weeks. His general condition remained unchanged. He then began to complain of "nasal catarrh." There was nasal obstruction, general malaise, and increase of œdema. Vomiting occurred on two or three occasions. There was no fever. This exacerbation lasted about ten days, and towards the end there was a definite diminution in the 24-hourly volume of urine to 325 c.cm. There was also a marked increase in protein loss.

He was seen by Mr. Norman Patterson, who found masses of polypi in both sides of the nose. Radiography showed no abnormality of the nasal sinuses. The polypi were removed under local anæsthesia on June 17th, 1931. Within the next few days his general condition began to show a steady and definite improvement which continued up to the time of his discharge on July 22nd, when there was no œdema and only a trace of albumin in the urine. During the whole time in hospital he was kept on a moderately full but strictly salt-free diet, with fluid up to two pints daily. Urea, 20 g. twice daily, was given over the period of June 10th–29th. The duration of the illness was about 18 weeks.

Six weeks after discharge from hospital he was back at work and feeling quite well. There had been no recurrence of the œdema and the urine was clear; the plasma protein and blood cholesterol had returned to normal limits (plasma protein, 6·55 per cent.; blood cholesterol, 0·22 per cent.). He was last seen on March 9th, 1932. He then stated that he felt perfectly well and had not noticed any further nasal obstruction since his operation. There was no œdema and the urine was clear.

DISCUSSION

The accompanying chart shows the sequence of events in the progress of the case. It illustrates the relationship of the recrudescence of the "nasal catarrh" with both the increase in weight due to œdema and the increase in protein output.* After the attack had subsided these returned to their previous levels. At this point however the patient was given 20 g. of urea twice daily. This was followed within 48 hours by a steady fall in weight, but no immediate diminution in the protein output. This latter only began after the removal of the polypi.

As an explanation of the course of this case there would seem to be several possibilities—namely:—

(1) That this was a case of nephrosis pursuing a relatively benign course with ultimate recovery and remaining uninfluenced by any treatment. This possibility must be admitted as such cases have been observed particularly in children.

(2) That the improvement was due to the administration of urea. Excellent results from the use of this drug have been reported by Volhard, Maclean, Wordley,[6] and others. An immediate fall in weight followed the administration of urea in this case. This was accompanied by a diminution in œdema and an increased urinary output, but there was no change in the protein output until the loss in weight had practically ceased.

(3) That this was a case of syphilitic nephrosis. Such cases were described by Munk,[3] but they occurred almost exclusively during the secondary stage of lues. Isolated cases have been reported as occurring years later. One of the cases of nephrosis reported in Russell's [7] series, a man aged 47, had been given about 15 injections of N.A.B. together with mercurial treatment for syphilis contracted 18 months before death, the Wassermann reaction being subsequently negative. Hurst [8] and Dowling [9] have reported cases of "syphilitic nephritis" occurring many years after the primary infection. Some of these responded to treatment with silver salvarsan and iodides in a very remarkable way. In the present case the primary lesion occurred 30 years

---

* The protein output was determined by daily estimations by the method of Kerridge.[4]

before, seven injections of N.A.B. were given nine months ago, and three injections of N.A.B. as shown in the chart. The Wassermann reaction was positive. It is difficult to believe that these last three injections were in any way connected with his recovery.

(4) That the nephrosis bore a definite relationship to the infection. Cases of chronic nephrosis in children are described by Clausen.[10] He believes them to follow infection with the *Staphylococcus aureus*, particularly of the paranasal sinuses. In Clausen's cases, however, it is not easy to be sure that all are true nephroses and some not nephrotic types of glomerulo-nephritis. In Bennett's [11] three cases, one was preceded by a chill. One of Russell's [7] cases was initiated by coryza, earache, and headache. In his discussion of "genuine nephrose" Volhard [12] states his belief that all such cases are really due to a chronic infection, could its site be determined.

Such a view of the ætiology in the present case is supported in the first place by the fact that the onset was preceded by a generalised infection. Secondly, by the relationship of the recrudescence of the infective process with the renal manifestations. Thirdly, by the culture of streptococci from the urine on two occasions. Lastly, by the very striking clinical improvement and corresponding diminution in protein loss which was observed to follow the operation. This case again demonstrates the possibility of complete recovery in patients with nephrosis, even after the persistence of the disease for many weeks.

In conclusion I have to thank Prof. Arthur Ellis for his kind permission to publish this case, and Mrs. P. Tookey Kerridge, Ph.D., for allowing me to make use of her observations on the protein output.

AGRANULOCYTIC ANGINA
COMPLICATING HODGKIN'S DISEASE

By Francis Pilkington, M.R.C.S. Eng.
HOUSE PHYSICIAN, KING'S COLLEGE HOSPITAL

This case is reported, first, because the complication of agranulocytic angina in Hodgkin's disease is an extreme rarity; secondly, because of the difficulty that was experienced in diagnosing the local condition owing to its resemblance to an ordinary diphtheritic membrane; and lastly, because I am not aware that a case has ever before been reported in a child; the condition nearly always occurs in middle-aged women.

PRIMARY HODGKIN'S DISEASE

The patient, a girl of 7 years, was admitted to King's College Hospital in July, 1930. Her past history consisted of measles two months previously, followed by a swollen neck. On admission there was a large mass of glands on each side of the neck, and discrete enlarged glands in both axillæ and groins. There was also evidence of some enlargement of the mediastinal glands. The spleen was not palpable. Lymphadenoma was diagnosed, and X ray treatment was started on August 5th, 1930. One local application to the enlarged glands was given nearly every week for a year, the dose varying from ¼–½ B.mm. In a few weeks the glands became smaller, and by the end of September they had practically disappeared. Other treatment consisted of liquor arsenicalis ♏ 2½ t.d.s., which was started on Sept. 1st and was continued on and off for nearly a year.

At the beginning of August, 1930, a blood count showed:—

Red cells	5,780,000	Polymorph. ..	56·8 %
White cells.. ..	1,800	Lymphocytes ..	27·6 %
Hæmoglobin ..	95 %	Eosinophil ..	15·2 %
Colour-index ...	0·83	Mononuclear ..	0·4 %

In October a leucocyte count showed leucocytes, 3000; polymorph., 57·2; lymphocytes, 36; eosinophil, 4·4; basophil, 0·8; and mononuclears, 1·6 per cent.

By this time the glands of the neck were normal, and the child was well enough to be discharged. She remained fit until the end of December, when she looked pale and run down and had a little enlargement of the submaxillary glands.

In February, 1931, the axillary and submaxillary glands were slightly enlarged, but in April they became smaller again and her general condition improved. In May, however, the spleen was palpable for the first time, and in June and July fresh enlarged glands frequently appeared in the neck, axillæ, and groins. They always disappeared with the local X ray treatment, but as soon as one group went a fresh group appeared elsewhere. All this time the child was really quite well, and was attending school.

AGRANULOCYTIC ANGINA

On Sept. 10th, 1931, the child developed a cough with pyrexia; generalised rhonchi were heard all over the chest, and there was some diminution of air entry at the right base. Two days later she developed a dirty white patch on the right anterior faucial pillar, and on Sept. 14th she was obviously ill and toxic, with a temperature of 103° F.

Her breath was foul, and there was a dirty white membrane the size of a shilling on the faucial pillar. A clinical diagnosis of diphtheria was made (although a swab taken on the 12th showed no Klebs-Löffler bacilli), and 30,000 units of antidiphtheritic serum were given intramuscularly. At this time her cervical glands were slightly enlarged and rather tender. She had a small gland below the right clavicle, and her spleen was just palpable. There were no other physical signs. The tonsils were healthy and her teeth in good condition.

On Sept. 16th the membrane was slightly more extensive. It was not particularly painful. Her cough was better, but her general condition was unchanged and her temperature was 103°. Two days later she was more toxic, and her breath was very offensive. By this time three throat swabs had all proved negative for Klebs-Löffler and Vincent's organisms, but a mixed infection of staphylococci, streptococci, and pneumococci was present in the third. It was then felt that the condition might be a streptococcal angina. On Sept. 21st her general condition was deteriorating, the temperature still being 103°–104° F. The affected area in the throat was definitely larger than on admission, its diameter being almost an inch. The membrane was beginning to separate, leaving an ulcerated and hæmorrhagic base. The membrane had disintegrated by Sept. 23rd, leaving a foul, stinking ulcer from which there was an occasional ooze of blood. A few minute petechiæ were noticed on the right forearm.

On Sept. 25th a blood count was done and gave the following astonishing result:—

Red cells	1,180,000	C.I.	1
White cells..	less than 100	Polymorph. ..	12·5 %
Hb.	24 %	Lymphocytes ..	87·5 %

The polymorphonuclears were stained by the Shato and Shoji benzidine method, and showed considerable granulation.

The diagnosis of agranulocytic angina was then made. A blood transfusion of 300 c.cm. was given immediately, and another of 430 c.cm. on Sept. 27th. Neither caused any improvement in the local or general condition. The throat became very foul and the ulcer more extensive, and some hæmorrhage occurred from it. She then developed a terminal broncho-pneumonia and died on Sept. 29th. Throughout the illness the temperature never dropped below 101° F., and it was usually 103°–104° F. The final blood count, done on the day before she died, showed :

Red cells	1,220,000	Platelets	45,000
White cells..	less than 50	Polymorph. ..	44 %
Hb.	22 %	Lymphocytes ..	56 %
C.I.	0·9		

The blood-Wassermann was negative, the van den Bergh normal, and a blood culture taken on Sept. 22nd was sterile after eight days' incubation.

Treatment.—On Sept. 14th she had 30,000 units, and on Sept. 16th 20,000 units of antidiphtheritic serum. On Sept. 18th 10 c.cm. of polyvalent antistreptococcal serum were given; on Sept. 20th 10 c.cm. of antiscarlet serum, and on Sept. 23rd 10 c.cm. of antipneumococcal serum. An arsenical throat paint was also used for the first week of the illness. No improvement, even temporary, could be detected as a result of any of this treatment.

POST-MORTEM REPORT

The autopsy verified the diagnosis of Hodgkin's disease.

There were slightly enlarged glands in the submaxillary region, along the right main bronchus, and along the upper border of the pancreas. All these glands were firm, smooth, and dark red or plum-coloured. Microscopically the normal anatomy of the gland was found to be replaced by a diffuse cellular infiltration, the chief cell being a moderately large round cell with a big and intensely dark nucleus, the other cells being pale endothelial cells. One or two immature Hodgkin giant cells were also seen. The glands were clearly lymphadenomatous, with superadded acute congestion. The spleen was three times its normal size, and looked like an infective spleen. There was hyperplasia of the splenic pulp, which contained many plasma cells and large round mononuclear cells, probably Hodgkin cells. No granular leucocytes were seen at all. Petechiæ were seen on the pericardium and in the kidneys. The bone-marrow from the middle of the tibia was red in colour. Megaloblasts and red cells were present, but there was not much evidence of myelocytic formation. There were also multiple erosions of the mucous membrane of the alimentary canal, a feature which has been noted before in agranulocytic angina.

COMMENTARY

This case is an example of the type of agranulocytic angina described by Schultz[1] in 1922, and believed by him to be a specific entity. The sudden onset of acute illness, the buccal inflammation and ulceration, the high fever and toxæmia, and the fatal termination are all typical of the disease. The condition is very rare (no other case can be traced in the records of this hospital from 1915–1931), and the occurrence of the disease in a child already suffering from Hodgkin's disease is probably unique.

A condition of agranulocytosis, however, without the sudden onset of a severe illness with inflammation and pyrexia, is not very uncommonly associated with aplastic anæmia, and is a sequel of bone-marrow failure.[2] The causes are those of aplastic anæmia in general, amongst which may be mentioned toxins from a septic focus, toxic substances (such as benzol) which depress the bone-marrow, and the use of radium and X rays in inappropriate doses.

The problem is whether agranulocytic angina is a primary and specific throat infection giving rise to the blood condition (as Schultz thought), or whether there is a pre-existing condition of agranulocytosis which would render the body particularly inefficient in dealing with a chance infection in the mouth or elsewhere. If the latter view is correct, it is surprising that agranulocytic blood counts are not more often found in the ordinary acute general or local infections such as pneumonia or carbuncle; for this type of infection occurs much more commonly than severe buccal infections, and presumably our primary agranulocytic patient would be just as liable to contract them as he would an ulcerated throat. Yet it is a fact that agranulocytic blood counts are very rare in these infections and, when they do occur, are always thought to be associated with a very virulent organism which inhibits the normal reaction of the body; in these patients there is a low temperature, not the high fever found in agranulocytic angina. The fact that such blood counts are not more often found is some evidence in favour of a specific buccal infection. Another argument for this hypothesis is that a primary leucocytosis with a shift to the left of the Arneth index is occasionally found in the early stage of agranulocytic angina.[3] This leucocytosis has presumably occurred before the specific toxin has become potent enough to depress the granulopoietic powers of the marrow.

Most of the recorded cases of agranulocytic angina have been in middle-aged women, and this fact may have some bearing on the problem, but the only suggestion that has been put forward[4] is that a certain degree of leucopenia with relative lymphocytosis is found in healthy women more often than in men, and that this might develop into agranulocytosis if suitable conditions prevailed. It is by no means certain, however, that women do possess these blood pictures more often than men.

The present case does not seem to give any clues. There was certainly some leucopenia soon after the diagnosis of Hodgkin's disease was made, but the percentage of granulocytes was above rather than below normal. This was, however, a year before the onset of the angina. The prolonged X ray treatment may have had a depressing effect on the bone-marrow, and had a blood count been made just before the acute illness it might have been agranulocytic. Dr. Parkes Weber, who has been kind enough to read through this paper, thinks that the X ray treatment probably played an important part in producing agranulocytosis.

My thanks are due to Prof. G. F. Still for permission to publish this case, and to Dr. W. P. H. Sheldon for criticism and advice.

HOSPITAL LIBRARIES.—The British Red Cross and Order of St. John Hospital Library is now supplying over 300,000 books and magazines to more than 1800 hospitals in England and overseas. Mr. Hagberg Wright, the chairman, has resigned and is being succeeded by Sir Theodore Morison.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL.—The new and chief feature of this hospital's work during the past year has been the development of research and the Rockefeller Foundation has made a grant for this purpose of 15,000 dollars annually for seven years on condition that approximately 18,500 dollars annually can be obtained from other sources. The number of patients attending in all departments has exceeded that in preceding years. The total expenditure for the whole institution amounted to £37,871 and the total income was £35,543, an increase of £12,383 on the previous year.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF LARYNGOLOGY AND OTOLOGY

THE summer meeting of these sections was held on June 10th and 11th at the Portsmouth Eye and Ear Hospital Southsea. On the first day Mr. WALTER HOWARTH, President of the Section of Laryngology, took the chair and a discussion on

Referred Pain

was opened by Mr. LIONEL COLLEDGE (London): John Hunter, he said, noted that suppuration in the antrum caused pain in the frontal sinus, and this kind of pain, confined to the trigeminal, was common. Thus, a patient had acute pain in the frontal sinus; the nose seemed normal, and the removal of an incisor tooth cured the pain immediately. Pain in the teeth often arose from the antrum; again, pain was often referred to the wrong tooth, though not across the middle line. Sometimes pain was referred to an ear which was not the seat of either inflammation or deafness. The source of referred pain in the ear was usually in the pharynx—e.g., calculus in the tonsil, epithelioma of the pharynx, or defective teeth. The classical example was an unerupted or partially erupted wisdom tooth, though any molar might cause pain in the ear, and even a bicuspid tooth might do so. Unerupted teeth could cause remarkable reflex symptoms.

One patient felt pain in the right mastoid process, which was tender; there was functional deafness in the right ear and left hemianæsthesia, in addition to pain in the face. The patient's dentist noted that one of her upper bicuspids was a milk tooth, which lay horizontally in the jaw, and when that had been removed her symptoms disappeared.

Other causes of pain in the ear were empyema of antrum or of the sphenoidal sinus, and malignant disease of the back of the tongue. Stated generally, a lesion in the area of distribution of the trigeminal nerve, of the glossopharyngeal or of the superior laryngeal branch of the vagus could cause pain referred to the ear.

Mr. Colledge related two cases to show how, on occasion, referred pain might prove of vital importance.

A boy, aged 14, had severe aural pain, but there was nothing to be seen wrong with the ear. At the autopsy pus was found around the sphenoidal sinus.

A man had an epithelioma in the lateral wall of the pharynx, low down. For six months he was treated by an aural surgeon for pain in the left ear, though that organ seemed normal in every respect. The operation, when at last it was undertaken, had to be very extensive, but the man still remained well after three years.

Why, Mr. Colledge asked, should the nervous system make this error in allocating the pain? Henry Head believed that pain was felt in the thalamus, and was analysed in the cerebral cortex. The speaker's suggestion was that when pain was referred wrongly it was to an area accustomed to experience pain; in other words, owing to lack of education in this respect, the natural perceptive area was not responsive, and there was a transfer of perception to a region accustomed to such manifestation.

Mr. ERIC WATSON-WILLIAMS (Bristol) said that when earache was complained of, and the ear was normal, the cause was problematical and had to be hunted for. It might be due to temporo-mandibular arthritis, or to mumps. The real trap lay in cases in which an ear was defective yet was not the cause of the pain. He had had two cases of vagus herpes oticus at the onset of lobar pneumonia. The former was very apt to simulate otitis media.

One of these cases was that of a boy, aged 14, who for three days had had severe pain in the ear. He had just had a cold, and when Mr. Watson-Williams saw him he was worse; he was giddy and was vomiting; his temperature was 104·4° F., and the respiration-rate 38. There was a slight sanious discharge from the ear, and extreme tenderness at the tip of the mastoid. The patient had been prepared in the theatre for a mastoid operation, but the case looked like one of pneumonia, and there were crepitations at the base of the lung. Operation was not performed, and 36 hours later the boy had typical pneumonia. There was a ruptured vesicle on the drum, which looked like a perforation.

When no local cause of pain could be found in the ear one should examine mouth, nose, pharynx, and larynx. Otitis media occurred in association with cancer of the nasopharynx and the Eustachian tube, and might be misleading. Sphenoidal sinusitis could easily be mistaken for otitis media, expecially in young subjects. Sometime unexplained referred pain was experienced in intracranial conditions; meningitis might cause pain in the ear, and this might be the first, indeed the only, localising sign. Finally, it was possible to meet with purely functional earache, though that was not strictly "referred pain."

Dr. PATRICK WATSON-WILLIAMS (Bristol) spoke of the importance, when a sinus was involved, of sucking out the contents and so relieving that tension which was so potent in determining the spread of infection. In cases in which pain was felt in an ear and nothing was seen there to account for it, the teeth and nose should always be examined, the latter by endo-rhinoscopy. Even when trouble was found in the ear, examination of the nose should never be omitted.

Mr. C. A. SCOTT RIDOUT (Southsea) laid emphasis on impaction or defects of teeth and on infection of the antrum in cases of pain referred to the ear; radiography, he said, was very important. He had seen several cases of functional ear pain, all in women of about 30 years of age. Some of those patients had "vacuum frontal sinusitis."

Dr. D. R. PATERSON (Cardiff) put in a plea for the recognition of the work on referred pain done by Prof. Francis Dixon, when professor of anatomy at Cardiff. He also pointed out that tonsils had often been removed, though healthy, because they were thought to be the source of aural pain, and that this had persisted nevertheless.

Mr. JOHN O'MALLEY (London) spoke of a patient whom he saw six weeks after having a tooth removed.

The extraction had been immediately followed by bleeding from the nose, and a day or two later by discharge of pus from the nose. Then the patient had pain in the roof of the nose and across the face into his ear, and this merged into the typical pain of frontal sinus trouble. Mr. O'Malley washed out a considerable quantity of pus from the antrum and the next day all the pain had disappeared.

Other speakers took part in the discussion and Mr. Colledge replied.

Polypi

Dr. G. SCOTT WILLIAMSON (London) read a paper on the Genesis of Polypi. It appeared, he said, that there must be some reason which made it inevitable that what were simple inflammatory swellings in other regions became polypoid in the nose and also in the cervix uteri. The chief factor was, he thought, the remoteness of the main blood-supply from its ultimate distribution. It was apt to be forgotten that hypertrophy took place in the various active glands of the nose and throat, as in other regions of the body. When hypertrophy of a structure had to take place within a limited area, as in the nose and throat, the manifestation was a polypoid one. Experimentally, an irritation which in an unrestricted area caused a simple sessile expansion of mucous membrane, produced in a confined zone polypoid formation. In 40 per cent. of cases of polypus examined there was found at the root of the polyp an adenoma or an adenoid hypertrophy—i.e., the primary lesion was apparently an overgrowth of the mucous glands or the superficial glands of the mucous membrane; the polyp was a large myxoid mass superimposed on an adenomatous formation. It was found experimentally that one had only to reduce the vascular supply of any hypertrophying gland to change its state from hypertrophy to hyperplasia, and once the latter was set up, the condition was on the high road to malignancy. In 17 cases he had been able to trace these stages.

Mr. W. M. MOLLISON (London) said he recognised, clinically, two types of polypi: (1) a small and rare kind seen in patients subject to hay-fever or spasmodic rhinorrhœa; these appeared high up in the nose, and he considered they were of mechanical origin. (2) The common type of polypus, which he had hitherto regarded as infective though he did not feel so certain after hearing Dr. Scott Williamson's paper. In addition there was a type of polypus associated with a good deal of pus—an indication of a change from a mild to a severe infection. He had not found any confirmation of Dr. Williamson's statement that many polypi might become malignant owing to hyperplasia having set in; practically never had he seen an ordinary polypus become malignant. His latest ideas regarding polypi had been upset by a case he saw recently.

The patient was a man aged 52. He had never had any functional nasal obstruction, but he began to complain of symptoms about the right antrum. At the age of 11 he had fallen from a height flat on to his face, severely distorting it and deflecting the septum to such an extent that one could not see into his nose; yet he had but little functional disability. Radiography showed in the antrum a smooth bulge from the right inferior wall of the antrum. The nasopharynx Mr. Mollison found to be normal, and there had been no nasal secretion. The antrum was opened through the canine fossa and in it there was a polypus, and nothing wrong with the mucous membrane except in that localised patch. Mr. Mollison carried out a submucous resection, and there was nothing behind it in the nose.

Mr. F. C. W. CAPPS (London) agreed with Mr. Mollison about the extreme rarity of malignant degeneration in polypi.

Dr. WATSON-WILLIAMS agreed that the clue to the causation of polypi was the anatomical difficulty of maintaining the lymph circulation. His own explanation of the cause of the ordinary nasal polypus with a narrow pedicle was that an infecting agent penetrated the epithelial layers and so got into the submucosa. He had been able to demonstrate cocci in the lymph spaces where an obstructive endolymphangitis was set up, and so an obstruction supervened. The fluid was thus exuded into the cellular spaces, and the result was intense œdema and protrusion from the surface. Chemical or mechanical irritants were also culpable.

Mr. A. LOWNDES YATES said a point of practical importance in this connexion was that the mucous membrane hypertrophied in length, breadth, and thickness, and so there was not room for expansion, and as the pressure was lowest in the lymphatic vessels that was the part cut off. In operating it was important to aim at giving room for the hypertrophy.

Inflammatory Conditions of the Ear

Mr. HAROLD BARWELL (London), introducing a discussion on Types of Inflammation causing Inflammatory Conditions of the Ear, confined himself to the frankly acute affections. What were the paths by which the inflammation might extend from one region to another? Spread by lymphatics or blood-vessels was so rare that it need not be considered in this connexion, though the ear could possibly be involved in the course of a septicæmia of nasal—as of any other—origin. Usually the inflammation reached the ear by continuity along the mucous membrane through the Eustachian tube or by discharges from a septic focus in the nose being blown through the Eustachian tube—the latter being, in his view, far the commoner. Violent or improper blowing of the nose was, he believed, the most important of all causes of aural inflammation arising from nasal inflammation. Three factors which might influence the extension of inflammation from the nose to the ear were: (1) the situation of the nasal lesion; (2) the previous condition of the ear and the Eustachian tube; (3) the virulence of the infecting micro-organisms. The last-named he regarded as much the most important. Apart from general virulence, some strains showed a special tendency to attack the ears.

Mr. T. H. JUST (London) believed that a clear-cut nasal infection, without any disease or abnormality in the nasopharynx, scarcely ever caused aural suppuration. In the cases in which nasal suppuration gave rise to aural suppuration he held that the infection was so severe that the whole mucosa of the upper air-passages was infected at the same time, and, because some stuffiness was present, patients localised the trouble to one side. The most common organism infecting the ear was the *Streptococcus pyogenes*; next came the pneumococcus, staphylococcus, and *B. influenzæ*; others were rare. Chronic antrum and ethmoid infection, per se, were rare causes, while frontal sinusitis was still rarer. Overlooked sphenoidal suppuration sometimes caused persistence of a chronic suppuration in the ears. Otitis media occurring simultaneously with a homolateral antrum infection always developed into an acute mastoid infection. From the aural point of view, an acute ethmoid condition was less virulent. Sinusitis, especially of the antrum, during an influenza epidemic, unless dealt with as conservatively as possible, led to acute otitis media and usually to drainage of the mastoid.

Mr. T. B. LAYTON (London) submitted a classification of infections of or through the upper respiratory tract, according to the patient's liability to develop an osteomyelitis of the mastoid bone due to the hæmolytic streptococcus. The most serious and anxious cases in all otology were those associated with influenza, in a general way, and there were two types of case which he dreaded. One was a flaming mastoid condition supervening on an attack of measles; the other an acute mastoid added to an influenzal or scarlatinal otitis media. Mr. Layton developed his idea of a filtrable virus.

Mr. E. MUSGRAVE WOODMAN (Birmingham) agreed that acute infections in the ear were often caused by faulty nose-blowing or by heavy douching of the nose.

Mr. GAVIN LIVINGSTONE (Seaford) demonstrated a model which he had made to illustrate the Nasal Air-way in the New-born Child.

Saturday was devoted to the examination and discussion of clinical cases, under the chairmanship of Mr. W. M. MOLLISON, President of the Section of Otology. Dr. J. R. B. HERN (London) showed a film illustrating a case of gross deflection of the trachea by a large tumour, and the attempt to remove it.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of this society on June 9th, with Dr. O. H. WOODCOCK, Vice-President, in the chair. paper entitled

ndividual Psychology and the Children's Clinic

was read by Miss RAYNER. She pointed out that a adical change in the upbringing of children had aken place within the last 100 years. The more nderstanding attitude of mind which had replaced he older methods of suppression had found practical xpression of recent years in the formation of child uidance clinics. Here the child was regarded as a nit in relation to the whole—whether he was good r bad depended largely upon his educators. The work of the clinic began where the child's natural ducators had failed to give him the understanding nd confidence required for courageous development. For the best results, therefore, the education and e-education of the educators must go hand-in-hand with that of the child. Where the parents could not be brought to coöperate, the child must either be immunised against them, or be removed from home until he was sufficiently self-reliant not to all back into his old ways of reaction. The child rought to the clinic was one who had not been rained to stand alone. His useless, antisocial behaviour was dictated by his underlying fears, and treatment was directed to the remedying of the defect in social feeling which nervous symptoms or delinquency betrayed. In this way healthy expression replaced a warped outlook upon life, egocentricity and undue authoritarianism were broken down, and the child was guided into freedom, self-reliance, and responsibility.

The CHAIRMAN said that he had been struck with the idea of the "open clinic" described by Miss Rayner. Dr. THOMAS LAWSON remarked that the adult had left the environment in which he acquired his neurosis, the child was still in it.—Miss N. K. HUNNYBUN thought that there might be some difficulty in connexion with the open clinic. The audience might be too critical, and the parents might be antagonised.—Dr. F. G. CROOKSHANK asked whether, in the inculcation of social feeling and encouragement in the clinics, the boys and girls were led to strive for their respective goals, or for the same one.—Miss BAINE said she had found that parents did not mind bringing up their problems in discussion groups, and that this procedure gave encouraging results.

Miss RAYNER said that in the open clinic the skilled and sympathetic psychiatrist was able to promote a friendly attitude on the part of the parent, and the audience did not tend to be critical. The question of the respective goals of the boy and girl did not arise in the clinic. The patients' difficulties were an indication of discouragement, and were regarded from this point of view.

REVIEWS AND NOTICES OF BOOKS

Anatomie pathologique

By MAURICE LETULLE, late Professeur Honoraire à la Faculté de Médecine de Paris. With the collaboration of L. NATTAN-LARRIER, Professeur au Collège de France; A. JACQUELIN, Médecin des Hôpitaux de Paris; L. DUCLOS, Ophtalmologiste Adjoint de l'Hôpital Chirurgical Gouin; and E.-P. NORMAND, Conservateur du Musée d'Anatomie Pathologique Générale Maurice-Letulle (Hôpital Boucicaut). Paris: Masson et Cie. 1931. Three volumes. Pp. 2346. Fr.600.

THESE three large and beautifully reproduced volumes are the final contribution to pathology of n author of great repute. Prof. Letulle's death occurred within a few weeks of his having completed he manuscripts, and the task of publication fell to is son Raymond Letulle in collaboration with the other authors. The work is the fruit of half a century f laborious research and observation. Prof. Letulle hroughout his long and active life as a teacher has kept foremost in his mind the importance of eaching the student to visualise at the bedside the hidden pathological changes occurring in the patient. n this book he has striven to show the active processes occurring in living tissues rather than static conditions evealed by museum specimens. No language is etter suited to this purpose than French, and Prof. Letulle uses it well. His descriptions are delightfully raphic and concise, his teaching dogmatic and ntrammelled by doubts or exceptions. Under his uidance pathology becomes simple, perhaps too imple. Confusing problems of the underlying nature f pathological processes are for the most part avoided, nd such notes on pathology as are introduced are ketchy. The work records essentially the observations and experience of Prof. Letulle; few references re made to the researches of others. For those who know enough to discriminate the work will provide an enormous fund of valuable information on morbid anatomy. The collection of beautiful drawings of microscopical preparations here included were executed by A. Karmanski, who worked for a large number of years with Prof. Letulle. Their inclusion makes this work a very complete atlas, the pictures being so well reproduced as to compensate for the occasional defects in the text.

A Handbook of Ocular Therapeutics

By SANFORD R. GIFFORD, M.A., M.D., Professor of Ophthalmology, Northwestern University Medical School, Chicago. London: Henry Kimpton. 1932. Pp. 272. 15s.

THIS book deals with the non-operative treatment of lesions of the eyes. Apart from local treatment—e.g., by drops—such measures as the administration of tuberculin, phototherapy, X rays, radium, and non-specific protein therapy are recommended for various conditions. Prof. Gifford believes strongly in milk injection for gonorrhœal ophthalmia whatever the age of the patient. For ophthalmia neonatorum he naturally and rightly lays stress on frequent efficient irrigation with a non-irritating fluid, but in his view the next most important measure is the use of foreign protein injections. One c.cm. of whole milk boiled for four minutes as an intramuscular injection, repeated every third day with an increasing dose according to the febrile reaction produced, is his prescription for every case, since he believes it to be impossible to pick out in advance the exceptional cases which do not get well with irrigation alone. Prof. Gifford agrees with Mr. Mayou that nitrate of silver should only be used in the later stage of the disease when the discharge is slight. He recommends milk injections also in doses up to 10 c.cm.

for adults with cyclitis and other conditions due to toxic infections, and in smaller doses for those cases of interstitial keratitis which do not respond to specific treatment, of which, by the way, he is a strong advocate.

In the main the treatment suggested is on orthodox lines. Mercurochrome is a favoured drug for conjunctivitis. A method of treating in-growing lashes by diathermy instead of the more prolonged and therefore more painful electrolysis is mentioned. The use of glaucosan in chronic glaucoma is discussed, also the intravenous injection of hypertonic solutions in acute glaucoma, with the warning that there is always danger in delaying operation too long. Prof. Gifford advocates simple massage of the eyeball in the presence of corneal scarring from superficial ulcers, in glaucoma as a temporary measure to gain time, and in cases of obstruction of the meibomian ducts. For syphilitic optic atrophy, generally considered a hopeless condition, he has been trying the injection of mercurial solutions into the cisterna magna through a needle inserted between the occipital bone and the atlas—with what success does not yet appear.

Synopsis of Midwifery and Gynæcology

Fifth edition. By ALECK W. BOURNE, M.B. Cantab., F.R.C.S. Bristol: John Wright and Sons, Ltd. 1932. Pp. 426.

THIS book has consistently improved with successive editions. It now contains all that is required for revision purposes by students up for final examinations and it should be brought to their notice. The new diagrams of the development of the early ovum are exceptionally good, although the legends might be expanded with advantage. The description of the technique of radium treatment for carcinoma of the cervix is a noteworthy addition which will be welcomed. The sections on ovarian physiology are not quite up to date and Heape's scheme for the œstrus cycle might now be omitted. The book has now reached a size beyond which a synopsis cannot be expanded without becoming less useful.

Sulphur Bacteria

A Monograph. By DAVID ELLIS, D.Sc. Lond., Ph.D., F.R.S.E., Professor of Bacteriology, Royal Technical College, Glasgow. London: Longmans, Green and Co., Ltd. 1932. Pp. 361. 21*s*.

THIS work deals with the microbiology of that group of bacteria which have sulphur granules present in their protoplasm. In the past this group has been neglected by bacteriologists, but now it would appear that the bacteriologist is held up for want of a more complete knowledge of biochemistry. Unfortunately, many problems of sulphur metabolism remain obscure. The isolation of the sulphydrol compounds towards the end of the last century and the work of Hopkins and his school on glutathione indicated the importance of sulphur in tissue metabolism. Recent observations, however, have plunged biochemists into confusion, since it is now by no means clear that glutathione plays any part in the normal oxidative processes of cells. The biochemist can hardly be expected to solve the bacteriologist's difficulties when he is already surrounded with so many of his own.

After a general introduction, Dr. Ellis devotes a chapter to sulphuretted hydrogen in connexion with sulphur bacteria, and then gives a good summary of our knowledge of the metabolism of the sulphur bacteria. He then describes the various methods of culture and the principles of classification. Much space and many illustrations are given to the leuco- and rhodo-thiobacteria, the intimate structure of the cell, and the influence of external phenomena such as light, are dealt with in one chapter, and the mechanics of ciliary movement and the colouring matter of the sulphur bacteria are discussed in another. A large bibliography and three separate indices conclude the volume.

La soufre en biologie et en thérapeutique

By M. LOEPER, Professeur à la Faculté de Médecine de Paris, Médecin de la Pitié; and L. BORY, Ancien chef de clinique à la Faculté de Médecine de Paris. Paris: G. Doin et Cie. 1932. Pp. 342. Fr.65.

THIS book deals with sulphur in all its various phases, starting with the flowers and finishing with glutathione, French thermal establishments and the value of drinking sulphurous spa waters. The illustrations range from pictures of chemical apparatus to photographs of people cured of psoriasis, and some very attractive looking pictures of French watering-places are included.

Pettibone's Text-book of Physiological Chemistry

Fifth edition. Revised and rewritten by J. F. MCCLENDON, Ph.D., Professor of Physiological Chemistry, Medical School, University of Minnesota, Minneapolis. London: Henry Kimpton. 1931. Pp. 370. 18*s*.

Prof. McClendon's revision of this well-known American work is an attempt to provide in one volume a handbook covering the elements of pure chemistry, and of organic and inorganic physical chemistry and physiological chemistry, together with a certain amount of practical work. Any such attempt can only result in the production of a rather superficial book. Some of the information provided is very sketchy and the style is distinctly American. The practical section is written in that irritatingly staccato manner which gives the student the impression that he is being bullied. For example, scattered throughout this section one sees between direct practical instructions such crisp words of command as "Write the equation," "What do you conclude?" and so on. The work has some useful points, but it is doubtful whether it will appeal to English students and teachers.

Die Elektro Chirurgie

By Prof. Dr. FRANZ KEYSER. Leipzig: Fischers Medizinische Buchhandlung. Pp. 238. M.52.

IN the early sections of this important book the technical side of surgical diathermy is clearly described. Prof. Keyser uses the spark gap apparatus giving damped waves, instead of the three electrode valve set, providing undamped waves which is much more expensive to manufacture. His results seem to be as good as those obtained with the excellent valve machines made in this country. The methods of employing diathermy are described in a thorough fashion, and the rest of the book gives an account of diathermy from a regional point of view, particularly in the treatment of cancer. The illustrations show a remarkable series of photographs of patients, before, during, and long after treatment. Prof. Keyser concludes his book by a discussion of accessory measures in the treatment of patients of which subject he has made a prolonged study.

FOR THE TREATMENT OF

CONJUNCTIVITIS, PAINFUL & TIRED EYES, & PINK EYE

PHENOLAINE EYE DROPS

Phenolaine is an antiseptic and anæsthetic: there is no effect on the pupil or accommodation and the drops may be used daily for years without any harmful effect on the cornea.

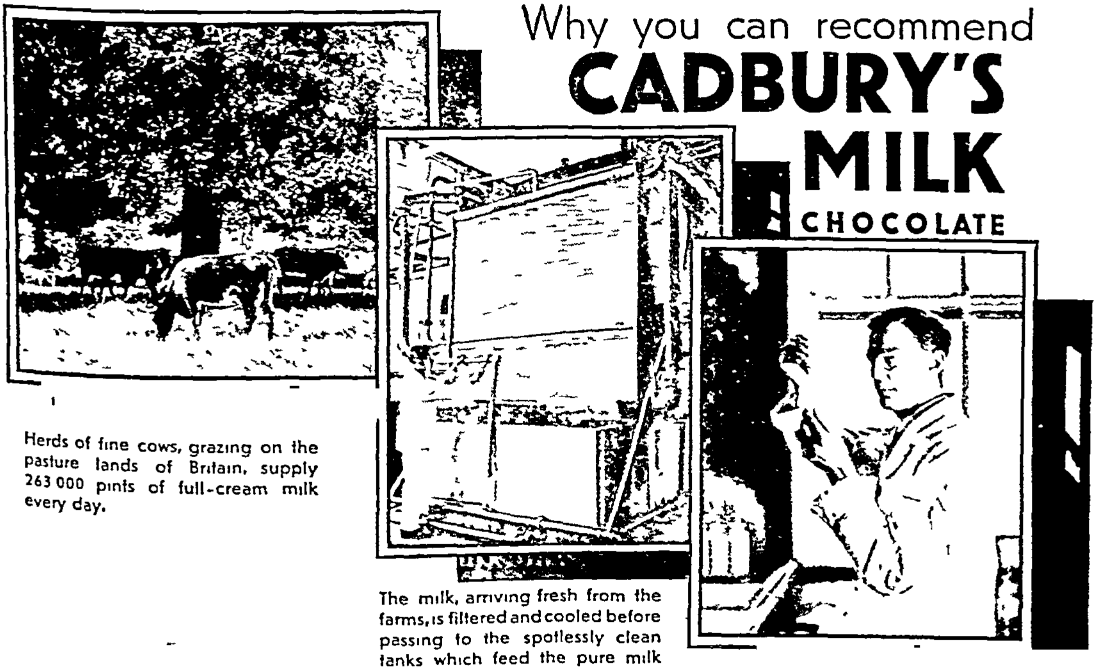
Why you can recommend

CADBURY'S MILK CHOCOLATE



Herds of fine cows, grazing on the pasture lands of Britain, supply 263 000 pints of full-cream milk every day.

The milk, arriving fresh from the farms, is filtered and cooled before passing to the spotlessly clean tanks which feed the pure milk to the Condensing Plant.

Constant analysis by qualified Chemists ensures highest quality of the milk and of all other ingredients

And that's why you'll say

I * * WANT * * CADBURY'S

Reminders and Suggestions

Products for use in General Practice

ADREPATINE A combination of Pluriglandular and Vegetable Extracts with Stovaine for the rational treatment of Hæmorrhoids.

Ointment: Tube with Canula—Suppositories: Box of 16.

HYPOTENSYL The active principles of Viscum (Gui) with Hepatic and Pancreatic Extracts for the treatment of conditions associated with High Blood Pressure.

Bottles of 50 Tablets.

IODOBESIN Iodalbumin with Pluriglandular Total Extracts. A safe and useful adjunct in the treatment of Obesity.

Bottles of 60 and 120 Tablets.

Gives good results in nearly all cases, whether of genital, thyroid, pituitary or undefined origin.

GYNOCALCION Calcium, Manganese and Phosphorus with appropriate Opotherapeutic Extracts for endocrin-sympathetic disturbances.

Bottles of 80 Dragees.

Supplied in two forms

Gynocalcion M—for irregularities of the Menopause.
Gynocalcion P—for the troubles of Puberty.

MYCOLACTINE A combination of Bile Extract, Yeast, and Lactic Ferments for the rational treatment of Alimentary Toxæmias, Intestinal Stasis and Constipation.

Bottles of 50, 500 and 1000 Tablets.

Literature and Samples on request from

THE ANGLO-FRENCH DRUG CO., Ltd.,

THE LANCET.

LONDON: SATURDAY, JUNE 18, 1932.

CENTENARY OF THE BRITISH MEDICAL ASSOCIATION

An advertisement on the cover of The Lancet of July 7th, 1832, announced a public meeting to be held at Worcester, for the purpose of taking into consideration the establishment of a projected medical association in that city. The objects in view were:—

1. The collection of useful information, whether speculative or practical, through original essays or reports of provincial hospitals, infirmaries, or dispensaries, or of private practice.
2. Increase of knowledge of the medical topography of England, through statistical, meteorological, geological, and botanical inquiries.
3. Investigation of the modifications of endemic and epidemic diseases, in different situations and at various periods, thus to trace, so far as the present imperfect state of the art will permit, their connexions with peculiarities of soil or climate, or with the localities, habits, or occupations of the people.
4. Advancement of medico-legal science, through succinct reports of whatever cases may occur in the provincial courts of judicature.
5. Maintenance of the honour and respectability of the profession, generally, in the provinces, by promoting the friendly intercourse and free communication of its members.

Wakley, in commenting on the scheme, described it as "masculine and comprehensive." He went on to say: "It lays a foundation for the congenial union of scientific research and professional honour, and addressed as it is to provincial practitioners—not by any means the least independent or least skilful members of the profession, who can doubt of its success, or, observing it, can fail to desire that its benevolent and intellectual promoters may live to witness this excellent example taken up and followed throughout the whole of the British dominions?"

The meeting marked the culmination of Sir Charles Hastings's whole-hearted efforts to unite the medical profession on a basis of scientific research. His first substantial act towards this end had been to found the *Midland Medical and Surgical Reporter*, a quarterly journal for collecting and utilising the valuable clinical material of the provincial hospitals. The new venture was the reaction of Hastings and his friends to the destruction of their journal through the failure of its printers and publishers. The meeting was duly held in the board-room of Worcester Infirmary, and was a great success. Hastings delivered a splendid address setting out practical proposals which were enthusiastically adopted. The meeting marked the birth of the Provincial Medical and Surgical Association, with 310 members from all over the country. The objects which these members had before their eyes at that moment were, first and foremost, the pooling of scientific observation and knowledge; contact with medicine in foreign countries; the study of disease in the community; medico-legal science; and the formation of a code of medical ethics. There was no idea that the Association should concern itself with medico-political matters or the qualification of medical practitioners; the first Medical Act still lay 26 years in the future. These then were the ideals of the new Association. It was emphatically and proudly a provincial body; it had arisen largely through the desire of provincial practitioners to assert themselves against the preponderance of London medical institutions and the pretensions of those who ran them. The president was, therefore, a senior physician or surgeon in one of the provincial towns within the circle of the Association, and the secretaries lived in Worcester, whence they superintended the publication of the *Transactions*. The first great change in the outlook of the new body occurred when its centre of gravity was shifted to London by the irresistible pull of the metropolis. In 1854 the *Journal*—the new name for the *Transactions*—was moved to London; at the annual meeting at York in 1855 there was a lively discussion but a proposal to change the name of the Association was defeated; the representation was improved but not to the satisfaction of a large number of members who did not attend. At a special meeting held in the autumn of the same year the name was changed to British Medical Association and sweeping changes were made in the constitution of the council. The further history of the Association—its work at the formation of the General Medical Council and the passing of the Act of 1886, its influence on the administration of the poor-law and the development of State medicine, to mention only a few of its adventures—is a record of strenuous and ever-widening service to the profession and the public. It is being ably written by Mr. E. Muirhead Little for the festival which is to be celebrated in London and at Worcester, the "faithful city" of Hastings, next month.

In this centenary year the annual representative meeting will be held as in 1930 at the headquarters building in London, but it will be the first year in which the beautiful Lutyens house in Tavistock-square has served the larger purposes of an annual meeting. This house, which was opened by the King in 1925, with its memorial gates dedicated by the Archbishop of Canterbury, provides a worthy home for the activities of a great professional organisation. For its acquirement the Association is largely indebted to the statesmanship of Sir Robert Bolam, then chairman of council. But even this house will not contain the centenary meeting, and Lord Dawson of Penn, the incoming President, will deliver his address at the Queen's Hall, Langham-place, while the centenary dinner will be held at the Albert Hall, on a scale much larger than any gathering that the Association has yet convened. A special pilgrimage to Worcester is being organised, and two memorials to the founder will be unveiled. The number and scope of the scientific sections is much greater than in ordinary years, as is fitting in a society founded originally to advance the science of medicine. It is interesting that forensic medicine, so little honoured in this country, is to have one whole morning given up to it by a special section. This step at least indicates that the study of medico-legal science, one of the Association's first objects, has not retrogressed in the last hundred years. We rejoice at the honour done to the Association in the knighthood conferred on Sir HENRY BRACKENBURY, the present chairman of council, who, in the intervals of a busy general practice, has done as much for the advancement of the Association as any man in its history. Heartfelt regret is felt at the retirement of Dr. ALFRED COX after 25 years' service as medical secretary, in which he has frequently been single-handed representative and champion of the Association before principalities and powers.

◆

WILHELM OSTWALD

OF the four great men who created the subject of classical physical chemistry—Van't Hoff, Arrhenius, Ostwald, and Nernst—only Nernst now survives. Van't Hoff died in 1911, Arrhenius in 1927, and now Ostwald has gone, having died on April 4th in his 79th year. Born at Riga in 1853, the son of a master cooper, WILHELM OSTWALD entered the University of Dorpat in 1872. Here he obtained the degree of *Philosophiae doctor* in 1878 and the post of lecturer. In 1881 he was called to the chair of chemistry in the Polytechnic at Riga, in 1887 to the special chair of physical chemistry in the University of Leipzig. He remained at Leipzig until his retirement from University life in 1905 at the comparatively early age of 52. The rest of his life (nearly 27 years) was spent at a pleasant house in the country, which he named "Landhaus Energie," in the neighbourhood of Grossbothen in Saxony.

OSTWALD's earliest scientific work was directed to the determination of the relative strengths ("affinities") of acids and bases by physical methods which did not interfere with the equilibrium state of the chemical system. For this purpose Julius Thomsen in Copenhagen had used the measurement of the heat evolved on mixing the interacting solutions, whilst J. H. Gladstone in England had employed measurements of light absorption. OSTWALD greatly extended this line of investigation by measuring the densities and refractivities of the solutions. He then took the important forward step of correlating the results obtained by these "statical" equilibrium methods with the results obtained by "kinetic" methods—e.g., the various effects of different acids in catalysing the rate of hydrolysis of esters (such as methyl acetate) in aqueous solution. A yet greater step was the discovery that the relative strengths or affinities of acids in aqueous solution, as determined by these various methods, ran parallel to their electrical conductivities, in aqueous solution, as measured by the alternating current method of Kohlrausch. Arrived at this result, OSTWALD at once perceived the importance o Arrhenius's theory of electrolytic dissociation—ionisation in solution, especially aqueous solution—and discovered his famous "Dilution Law," whic showed that the variation with dilution of th degree of ionisation of a "weak" acid or base i aqueous solution, as determined by the electric method of Arrhenius, could be described by th law of chemical equilibrium. This discovery len great support to the explanation which the theor of Arrhenius gave of the anomalous osmotic effect which Van't Hoff had observed in aqueous solu tions of many electrolytes. OSTWALD soon becam the great protagonist of the new ionisation theor and he and his numerous pupils published lon series of researches in this field, many of thes throwing a new light on the electric potenti differences existing between metals and solution of their salts. The theory of chemical reactio velocity in solution was greatly developed an extended, whilst investigations of this nature le OSTWALD to the last great series of researches a Leipzig—namely, those on catalytic action. Thi was always a subject very close to his heart.

The discoveries of OSTWALD and his school hav had a profound influence on physiology and med cine. The many effects produced by salts, acids and bases in blood and lymph and in the interior of cells and organs are largely due to the ions an are concerned with ionic equilibria. The funda mental actions of enzymes are catalytic actions and the operations of these enzymes are largel controlled by the hydrogen-ion concentration Life is a process requiring for its balance and pois a very delicate regulation of coördinated ioni concentrations and ionic equilibria, whilst a understanding of the coördinated flux of meta bolism requires a profound knowledge of the law of chemical reaction velocity. Classical physica chemistry, the science of which WILHELM OSTWALD was the eminent organiser and one of the chief founders, is one of the pillars on which the great structure of modern physiology and medicine rests to-day.

◆

INSTRUCTION IN OPHTHALMIA NEONATORUM

OF all the causes of blindness in childhood and youth there is no doubt that gonococcal infection of the conjunctiva at birth still takes a chief place. The proportion on the roll of the London County Council blind schools last year with blindness due to this cause was 45 out of 218, or about 20 per cent. At the Swiss Cottage school for the blind five years ago the proportion for past and present pupils was 57 out of 255—substantially the same percentage. But now some improvement appears to have begun, for according to Mr. M. S. MAYOU, although the number of cases of ophthalmia neonatorum notified in London has not diminished during the last 15 years, the number that end in blindness has decreased to less than one half. It may be fair to infer that the larger proportion of cures is due to more efficient care. By far the most important part of treatment consists in frequent irrigation of the eyes during the acute stage, the frequency being based upon the amount of discharge. To secure this it is in most cases desirable for the infant to be admitted without delay to a hospital, and since the disease begins during the first few days of life, it is necessary for the mother to be admitted also. The problem presents obvious difficulties, but they have been overcome in some institutions, notably (from 1908) at St. Paul's Eye Hospital, Liverpool, and in London at St. Margaret's Hospital, an institution set aside by the L.C.C. for this purpose. Since this was opened in 1918 it has been utilised to an increasing extent, so that, in 1930, out of 617 notified cases in London, 196 were admitted to the hospital. The chief difficulty is that the patients are not sent in early enough. When St. Margaret's was first opened the average age at which the infant was admitted was three weeks, and although there has been improvement since, there is still too large a proportion of cases admitted with corneal ulceration. Mr. **Mayou** complains that it is difficult to get midwives to realise that the mother and infant can be moved safely by means of an ambulance on the third or fourth day after the birth of the child. Another hindrance to serious treatment is the difficulty found by the practitioner, especially if newly qualified, in gaining experience of the subject. The medical student may go through his whole course of training without seeing a case. It was this that led the Council of British Ophthalmologists some years ago to petition the General Medical Council in the following way:

> That it should be made compulsory for all students to attend once at least one of the ophthalmia neonatorum centres for practical instruction in the management and treatment of these cases, the most convenient time in the curriculum being during attendance at the course on fevers.

The matter came before the Council again at its recent summer session as we noted last week (p. 1272), when Mr. **Bishop Harman** remarked that at the West London Hospital, where formerly numbers of these cases were received, now there was not one a year. Mr. H. L. **Eason**, who had a similar tale to tell from Guy's, agreed that no teaching was adequate unless the students saw the disease itself. The extern maternity work of general hospitals is now, he said, so well run that cases of ophthalmia neonatorum are never seen. Unfortunately the dearth of cases seen by students is not due to its general rarity. About 100 cases are notified week by week in England and Wales. What must be done is to bring the student and the disease together. The General Medical Council decided not to lay down a hard-and-fast rule applicable to all medical schools, but the opinion was expressed that it is the business of the teacher in the ophthalmological clinic to make the necessary arrangements for his pupils to see these cases. Obviously facilities must vary locally. The essential matter is that in all medical schools they should exist.

ANNOTATIONS

MENTAL DEFICIENCY AND STERILISATION

The Wood Committee estimated the number of mentally defective persons, including children, in Great Britain as about 300,000, and of these we know, from the Minister of Health, that 97,310 were last New Year actually "ascertained" by local authorities, and 33,356 under guardianship or in institutions. Several times during this and last Parliamentary session the Minister has been asked if he was prepared to investigate the question of the sterilisation of the unfit and, if found desirable, to introduce legislation to eradicate the evil; and on Feb. 15th the Parliamentary secretary announced the Minister's intention to arrange for a preliminary investigation of the scientific issues involved as the first step towards a full and authoritative inquiry into the problems of mental deficiency, in which sterilisation is only one of several inter-related questions. It is now announced that the Board of Control, with the approval of the Minister, have appointed a committee constituted as follows:—

Mr. L. G. **Brock**, chairman of the Board of Control (chairman).

Mr. **Wilfred Trotter**, M.S., F.R.S., surgeon to University College Hospital; member of the Medical Research Council.

Mr. R. A. **Fisher**, Sc.D., F.R.S., of the Statistical Dept., Rothamsted Experimental Station.

Dr. A. F. **Tredgold**, F.R.C.P., associate physician in psychological medicine, University College Hospital.

Miss **Ruth Darwin**, commissioner of the Board of Control.

Dr. E. W. **Adams**, medical officer, Ministry of Health.

Dr. R. H. **Crowley**, F.R.C.P., senior medical officer, Board of Education.

Dr. E. O. **Lewis**, D.Sc., commissioner of the Board of Control.

Mr. F. Chanter of the Board of Control will act as Secretary.

The terms of reference are "to examine and report on the information already available regarding the hereditary transmission and other causes of mental disorder and deficiency; to consider the value of sterilisation as a preventive measure having regard to its physical, psychological, and social effects and to the experience of legislation in other countries permitting it; and to suggest what further inquiries might usefully be undertaken in this connexion."

THE TONSILS AND PHYSIQUE

It is generally accepted that many of the arguments put forward in favour of the removal of tonsils are to-day in need of critical examination. A paper by Dr. Ruby L. Cunningham[1] gives an account of an attempt to measure some of the effects of the operation by a study of the histories and physical measurements of young women entering the University of California from 1920 to 1929. The histories she dealt with in a previous paper,[2] but the present comparison of physical measurements and menstrual experiences should, in some ways, carry more conviction, since histories are liable to be faulty through defective interpretation and memory, an error from which the present data are free. From consideration of the histories it was concluded that the contention that normal tonsils are an aid in resisting disease was not supported, while, per contra, there was no evidence in favour of the belief that their removal closes a portal of entry for infectious and respiratory diseases. The present study adds that the condition of the tonsils—whether normal, absent, or pathological—has little effect on the physical condition of these young women of college age, from 15 to 35 years. For example no significant relationship was found between the tonsillar condition and the proportion of women with enlarged cervical glands (about 20 per cent. in each group), or between the tonsillar and the menstrual conditions as judged by the mean duration of menstruation, the amount of pain, the amount of flow, and the amount of irregularity. The incidence of aural and dental conditions showed no variation. There is a suggestion that those with pathological tonsils include a larger number with thyroid glands showing adolescent enlargement, and that those whose tonsils had been removed attained a slightly greater mean height (only one-tenth to one-fifth of an inch). The most perfect nasal structures were, naturally enough, found in the group with normal tonsils, but, on the other hand, those with pathological tonsils had on the average better vision and fewer ocular defects and their mean weight was somewhat greater. Those whose tonsils had been removed had somewhat less acne than those with normal tonsils—a slight difference but one that is statistically significant. Obviously the difficulty mainly lies in the interpretation of such differences, for it is impossible to detect what basis of selection, in the past, determined whether tonsils should be removed or not. No doubt a part is played by such factors as heredity, place of residence, past health history, standards of living and attitude towards medical care. Unless the groups are initially equal the effect of the removal or non-removal cannot be clearly determined. At least it can be said that no broad differences are to be observed in this study, and the effect of normal tonsils in augmenting growth, or of diseased tonsils in retarding development, is not apparent.

---

[1] Arch. Int. Med., March, 1932, p. 453.

[2] Ibid., 1931, xlvii., 513.

It is possible that in this country a regional study might confirm these findings. In some counties, notably in Derbyshire, the proportion of school-children referred for treatment is much higher than in others. In the five years 1926 to 1930, the figures for Derbyshire were 89·8, 113·8, 118·7, 143·7, and 140·2, per 1000 routine inspections, the corresponding figures for England and Wales being 54·6, 60·9, 63·0, 66·8, and 66·5. The operation-rate for 1931 in Derbyshire is 3·5 per cent. Dr. W. M. Ash, in the annual report which we noticed last week, says that he has been unable to satisfy himself that many of the conditions for which tonsillectomy is advised are in any way benefited by the operation. In a large group of children he found that the ordinary respiratory troubles of the larynx, bronchi, and lungs were not less frequent in children whose tonsils and adenoids had been removed, nor was the incidence of the common infectious diseases affected with the possible exception of diphtheria. Little improvement in nutrition was noticed and improvement was recorded only in those children whose symptoms had been mouth-breathing, colds in the head, sore-throat, and otitis. His second indictment—that the operation is no trivial one and that post-operative complications though not common are often alarming—has less force, since of his list of sequelæ some could not fairly be attributed to the operation, and some would be less likely to occur in areas where facilities for in-patient treatment are provided. Dr. Ash has now taken the practical step of instructing his assistants to divide cases of enlarged tonsils and adenoids into two groups. Those classified as not urgently requiring operation are to be given advice on diet, with especial reference to vitamins A and D, taught to breathe properly, and treated for any septic dental conditions; they are to be re-examined not less than six months later. As a result of this alteration in procedure the proportion of cases referred for treatment fell to 83·1 per 1000 routine inspections in 1931, though the scheme had only been in operation for six months of that year. This conservative tendency is in accord with the scepticism about the value of indiscriminate tonsillectomy which studies such as that of Dr. Cunningham serve to strengthen.

EXPERIMENTAL CANCER

The report of the Yorkshire Council of the British Empire Cancer Campaign for 1931–1932 contains accounts of the experimental work carried out in the two centres, Leeds and Sheffield. Dr. J. S. Young summarises the results of his experiments on the production of epithelial hyperplasia in the lungs of rabbits by stating that the equilibrium of the resting epithelial cell is less susceptible to disturbance by an alkaline medium than by an acid one. In both cases, however, a very gross interference is essential before an epithelial reaction begins, greatly exceeding any change of the kind which might be expected to occur under natural conditions. Dr. Berenblum has continued and confirmed his investigations on the anticarcinogenic action of mustard gas and allied substances. In view of the misleading interpretation which has been given to the term "anticarcinogenic action," it may be pointed out that it describes the local inhibition of the development of tar cancer when these anticarcinogenic substances are applied alternately with tar to a circumscribed skin area. The phenomenon, interesting as it is from a theoretical point of view, has, therefore, at present no practical application.

The factor of susceptibility to carcinogenesis, the importance of which has recently been recognised, has been studied by breeding from mice which develop tar cancer at an early stage and then comparing the rate and frequency with which the offspring of such mice develop tar cancer in comparison with the ordinary laboratory stock. The results obtained so far indicate that mice bred from parents with early tar tumour develop tar warts sooner than the stock-bred mice. The report of Prof. E. Mellanby from the Sheffield centre deals mainly with the work of Mr. A. F. Watson, Ph.D. He has obtained a highly carcinogenic synthetic tar by subjecting purified turpentine to a temperature of 850° C. and subsequent steam distillation of the product. The tar obtained in this way appears to be an agent of extraordinarily high carcinogenic potency, not only for mice and rabbits, but also for rats, which have so far proved very resistant to the experimental production of skin cancer. In experiments on the effects of different diets on the development of tar cancer it was found as a general rule that the development and growth of tar cancer was most active in animals kept on diets which improved the general condition of the animals, and was conversely least active in animals kept on diets which adversely affected this general condition. Apart from this, no specific relation between the addition of different foodstuffs to a basal ration and the development of tar cancer could be established, except in one instance. The addition of fresh liver definitely accelerated the development of tar cancer in mice. This effect was observed only with fresh ox livers and not with frozen or chilled livers. Lean beef muscle and ox spleen had no accelerating effect. These interesting results confirm some earlier observations recorded by Prof. Maisin, of Louvain, but Dr. Watson's experiments have been carried out on a much larger scale and have also revealed certain fallacies which may have prevented other workers from confirming Maisin's observations.

The Yorkshire Council is to be congratulated on the activity and scientific soundness with which the investigation of cancer is carried on in their research centres.

THE STUDY OF TUBERCULOSIS BY GENERATIONS

IN the early 'nineties of last century Dr. K. F. Andvord launched his then revolutionary theory that the fatal tuberculosis of adult life is usually contracted in early childhood. Since then he has been tireless in exploring the epidemiology of tuberculosis, mainly on statistical lines, and his latest publication[1] raises many questions to which he finds stimulating counter-questions rather than cut-and-dried answers. His main thesis is that tuberculosis is a "generational" disease, and that once the degree of infection is known in a given age—say the first five years of life—then the fate of this generation, as far as its future tuberculosis mortality is concerned, can be forecast for the rest of its life.[2] According to this doctrine of morbid predestination, which is, after all, merely an expansion of the teaching that the tuberculosis of adult life is contracted in childhood, the first effects of any successful campaign against tuberculosis will be noted only in the youngest generations; the fate of the older generations has already been sealed. Only after preventive measures have been enforced for, say, a score of years will a generation in its twenties show a lowered tuberculosis mortality. With regard to the primary infections occurring in adult life, Dr. Andvord makes some curious and inexplicable comparisons between the three Scandinavian countries. In Denmark, Pirquet tests have hardly ever shown clinical manifestations of tuberculosis in recruits whose reaction changed from negative to positive during military service. In Sweden, barely 4 per cent. of recruits in this category have shown clinical signs of tuberculosis during the transition from a negative to a positive reaction. But in Norway some 8 to 10 per cent. of probationer nurses celebrate their passage from the ranks of the negative reactors to those of the positive reactors by falling ill. In other words, the adult Dane shows no other response to his first infection with tuberculosis than a positive Pirquet reaction, while a goodly proportion of Norwegians coming into contact with tuberculosis for the first time in adult life supplement their newly acquired positive reactions with serious and clinically demonstrable signs of tuberculosis. If the generation born in the period 1900–1905 in the three Scandinavian countries be followed into their twenties, similar marked differences will be found. In the period 1920–1925 this generation had a tuberculosis mortality of 42·8 per 10,000 in Norway. The corresponding figure for Sweden was only 27·1 and for Denmark it was down to 14·9. Considering how much the Scandinavian countries have in common, it is amazing that in one and the same generation the tuberculosis mortality should be approximately three times higher in Norway than in Denmark. Within her own boundaries, Norway shows striking differences in her tuberculosis mortality, that of the far north being twice that of the south of Norway. The still Pirquet-negative adult native of the north of Norway faces tragedy at his first exposure to tuberculosis, and Dr. Andvord abandons his theory of childhood infection to the extent of estimating 25 to 30 per cent. of all the deaths from tuberculosis in the north of Norway as being sequels to primary infections in adult life. On the other hand, the adult Pirquet-negative Dane seems to escape when he encounters tuberculosis for the first time. Faced by these apparent contradictions, Dr. Andvord is driven to the conclusion that "the Pirquet reaction tells us only whether a person is infected or not with tuberculosis; but it tells us little or nothing about susceptibility, prognosis, and the clinical course of a case, for with the same Pirquet reaction one may encounter the greatest contradictions in the course of the disease and its prognosis."

ATROPHIC ARTHRITIS AND ITS RELATIONS

ANY effort to clarify ideas about arthritis is welcome, and some really valuable statistical work, treating each aspect of the disease separately, has been undertaken by Dr. Millard Smith at the University Hospital, Ann Arbor, Michigan. The present material is obtained from the first 102 cases of a total series of 612. They have been observed over a period of three years, and the results are recorded in three consecutive papers.[1] The study mainly concerns the "non-articular" aspect of so-called atrophic arthritis on the generally accepted principle that the joint changes are only a manifestation of a profound physiological disturbance involving the autonomic nervous system, the vascular system, and the smooth musculature. Millard Smith begins with a classification of arthropathies. It seems unfortunate that we should be burdened with yet another classification but, as he says, nearly every writer uses a different nomenclature and it is essential that he should make it clear which he has adopted. The first or introductory paper proceeds along the following lines: distribution of cases by sex, incidence by age-groups, habitus, complexion, occupation and social status, distribution of sub-types of atrophic arthritis at the onset of the disease and when last seen, with a further study of the changes in the type of the arthritis at the onset and when finally observed; it ends with a study of the blood and the basal metabolism. Much of this has been done before, and nothing strikingly different from previous observations emerges; its value lies chiefly in confirming views already held. The second paper deals with constitutional defects. Millard Smith points out how unfortunate it is that the theory of focal infection has blinded observers to physiological deviations from the normal and consequently the constitutional aspect of the disease. He emphasises R. L. Jones's accurate clinical account of the condition by reporting similar findings in this group of 102 cases, thereby paving the way to a more liberal theory of the disease than that based on the limited one of joint infection. He lays stress especially on the regular prodromal period and its constitutional signs, which prevail and become exacerbated in the arthritic stage. He finds the disease has strong familial tendencies and the data on the allergic traits suggest an abnormal reactibility common to a significant number of patients. Allergic manifestations are evidence of a peculiar reactibility on the part of the autonomic nervous system, the vascular system, the smooth muscle system, and Millard Smith demonstrates by a diseases. The present study adds that the condition of the tonsils—whether normal, absent, or pathological—has little effect on the physical condition of these young women of college age, from 15 to 35 years. For example no significant relationship was found between the tonsillar condition and the proportion of women with enlarged cervical glands (about 20 per cent. in each group), or between the tonsillar and the menstrual conditions as judged by the mean duration of menstruation, the amount of pain, the amount of flow, and the amount of irregularity. The incidence of aural and dental conditions showed no variation. There is a suggestion that those with pathological tonsils include a larger number with thyroid glands showing adolescent enlargement, and that those whose tonsils had been removed attained a slightly greater mean height (only one-tenth to one-fifth of an inch). The most perfect nasal structures were, naturally enough, found in the group with normal tonsils, but, on the other hand, those with pathological tonsils had on the average better vision and fewer ocular defects and their mean weight was somewhat greater. Those whose tonsils had been removed had somewhat less acne than those with normal tonsils—a slight difference but one that is statistically significant. Obviously the difficulty mainly lies in the interpretation of such differences, for it is impossible to detect what basis of selection, in the past, determined whether tonsils should be removed or not. No doubt a part is played by such factors as heredity, place of residence, past health history, standards of living and attitude towards medical care. Unless the groups are initially equal the effect of the removal or non-removal cannot be clearly determined. At least it can be said that no broad differences are to be observed in this study, and the effect of normal tonsils in augmenting growth, or of diseased tonsils in retarding development, is not apparent.

[2] See THE LANCET, 1930, ii., 146.

[1] New Eng. Jour. Med., 1932, ccvi., 103, 160, 211.

It is possible that in this country a regional study might confirm these findings. In some counties, notably in Derbyshire, the proportion of school-children referred for treatment is much higher than in others. In the five years 1926 to 1930, the figures for Derbyshire were 89·8, 113·8, 118·7, 143·7, and 140·2, per 1000 routine inspections, the corresponding figures for England and Wales being 54·6, 60·9, 63·0, 66·8, and 66·5. The operation-rate for 1931 in Derbyshire is 3·5 per cent. Dr. W. M. Ash, in the annual report which we noticed last week, says that he has been unable to satisfy himself that many of the conditions for which tonsillectomy is advised are in any way benefited by the operation. In a large group of children he found that the ordinary respiratory troubles of the larynx, bronchi, and lungs were not less frequent in children whose tonsils and adenoids had been removed, nor was the incidence of the common infectious diseases affected with the possible exception of diphtheria. Little improvement in nutrition was noticed and improvement was recorded only in those children whose symptoms had been mouth-breathing, colds in the head, sore-throat, and otitis. His second indictment—that the operation is no trivial one and that post-operative complications though not common are often alarming—has less force, since of his list of sequelæ some could not fairly be attributed to the operation, and some would be less likely to occur in areas where facilities for in-patient treatment are provided. Dr. Ash has now taken the practical step of instructing his assistants to divide cases of enlarged tonsils and adenoids into two groups. Those classified as not urgently requiring operation are to be given advice on diet, with especial reference to vitamins A and D, taught to breathe properly, and treated for any septic dental conditions; they are to be re-examined not less than six months later. As a result of this alteration in procedure the proportion of cases referred for treatment fell to 83·1 per 1000 routine inspections in 1931, though the scheme had only been in operation for six months of that year. This conservative tendency is in accord with the scepticism about the value of indiscriminate tonsillectomy which studies such as that of Dr. Cunningham serve to strengthen.

EXPERIMENTAL CANCER

The report of the Yorkshire Council of the British Empire Cancer Campaign for 1931–1932 contains accounts of the experimental work carried out in the two centres, Leeds and Sheffield. Dr. J. S. Young summarises the results of his experiments on the production of epithelial hyperplasia in the lungs of rabbits by stating that the equilibrium of the resting epithelial cell is less susceptible to disturbance by an alkaline medium than by an acid one. In both cases, however, a very gross interference is essential before an epithelial reaction begins, greatly exceeding any change of the kind which might be expected to occur under natural conditions. Dr. Berenblum has continued and confirmed his investigations on the anticarcinogenic action of mustard gas and allied substances. In view of the misleading interpretation which has been given to the term "anticarcinogenic action," it may be pointed out that it describes the local inhibition of the development of tar cancer when these anticarcinogenic substances are applied alternately with tar to a circumscribed skin area. The phenomenon, interesting as it is from a theoretical point of view, has, therefore, at present no practical application.

The factor of susceptibility to carcinogenesis, the importance of which has recently been recognised, has been studied by breeding from mice which develop tar cancer at an early stage and then comparing the rate and frequency with which the offspring of such mice develop tar cancer in comparison with the ordinary laboratory stock. The results obtained so far indicate that mice bred from parents with early tar tumour develop tar warts sooner than the stock-bred mice. The report of Prof. E. Mellanby from the Sheffield centre deals mainly with the work of Mr. A. F. Watson, Ph.D. He has obtained a highly carcinogenic synthetic tar by subjecting purified turpentine to a temperature of 850° C. and subsequent steam distillation of the product. The tar obtained in this way appears to be an agent of extraordinarily high carcinogenic potency, not only for mice and rabbits, but also for rats, which have so far proved very resistant to the experimental production of skin cancer. In experiments on the effects of different diets on the development of tar cancer it was found as a general rule that the development and growth of tar cancer was most active in animals kept on diets which improved the general condition of the animals, and was conversely least active in animals kept on diets which adversely affected this general condition. Apart from this, no specific relation between the addition of different foodstuffs to a basal ration and the development of tar cancer could be established, except in one instance. The addition of fresh liver definitely accelerated the development of tar cancer in mice. This effect was observed only with fresh ox livers and not with frozen or chilled livers. Lean beef muscle and ox spleen had no accelerating effect. These interesting results confirm some earlier observations recorded by Prof. Maisin, of Louvain, but Dr. Watson's experiments have been carried out on a much larger scale and have also revealed certain fallacies which may have prevented other workers from confirming Maisin's observations.

The Yorkshire Council is to be congratulated on the activity and scientific soundness with which the investigation of cancer is carried on in their research centres.

THE STUDY OF TUBERCULOSIS BY GENERATIONS

IN the early 'nineties of last century Dr. K. F. Andvord launched his then revolutionary theory that the fatal tuberculosis of adult life is usually contracted in early childhood. Since then he has been tireless in exploring the epidemiology of tuberculosis, mainly on statistical lines, and his latest publication [1] raises many questions to which he finds stimulating counter-questions rather than cut-and-dried answers. His main thesis is that tuberculosis is a "generational" disease, and that once the degree of infection is known in a given age—say the first five years of life—then the fate of this generation, as far as its future tuberculosis mortality is concerned, can be forecast for the rest of its life.[2] According to this doctrine of morbid predestination, which is, after all, merely an expansion of the teaching that the tuberculosis of adult life is contracted in childhood, the first effects of any successful campaign against tuberculosis will be noted only in the youngest generations; the fate of the older generations has already been sealed. Only after preventive measures have been enforced for, say, a score of years will a generation in its twenties show a lowered tuberculosis mortality. With regard to the primary infections occurring in adult life, Dr. Andvord makes some curious and inexplicable comparisons between the three Scandinavian countries. In Denmark, Pirquet tests have hardly ever shown clinical manifestations of tuberculosis in recruits whose reaction changed from negative to positive during military service. In Sweden, barely 4 per cent. of recruits in this category have shown clinical signs of tuberculosis during the transition from a negative to a positive reaction. But in Norway some 8 to 10 per cent. of probationer nurses celebrate their passage from the ranks of the negative reactors to those of the positive reactors by falling ill. In other words, the adult Dane shows no other response to his first infection with tuberculosis than a positive Pirquet reaction, while a goodly proportion of Norwegians coming into contact with tuberculosis for the first time in adult life supplement their newly acquired positive reactions with serious and clinically demonstrable signs of tuberculosis. If the generation born in the period 1900–1905 in the three Scandinavian countries be followed into their twenties, similar marked differences will be found. In the period 1920–1925 this generation had a tuberculosis mortality of 42·8 per 10,000 in Norway. The corresponding figure for Sweden was only 27·1 and for Denmark it was down to 14·9. Considering how much the Scandinavian countries have in common, it is amazing that in one and the same generation the tuberculosis mortality should be approximately three times higher in Norway than in Denmark. Within her own boundaries, Norway shows striking differences in her tuberculosis mortality, that of the far north being twice that of the south of Norway. The still Pirquet-negative adult native of the north of Norway faces tragedy at his first exposure to tuberculosis, and Dr. Andvord abandons his theory of childhood infection to the extent of estimating 25 to 30 per cent. of all the deaths from tuberculosis in the north of Norway as being sequels to primary infections in adult life. On the other hand, the adult Pirquet-negative Dane seems to escape when he encounters tuberculosis for the first time. Faced by these apparent contradictions, Dr. Andvord is driven to the conclusion that "the Pirquet reaction tells us only whether a person is infected or not with tuberculosis; but it tells us little or nothing about susceptibility, prognosis, and the clinical course of a case, for with the same Pirquet reaction one may encounter the greatest contradictions in the course of the disease and its prognosis."

ATROPHIC ARTHRITIS AND TS RELATIONS

ANY effort to clarify ideas about arthritis is welcome, and some really valuable statistical work, treating each aspect of the disease separately, has been undertaken by Dr. Millard Smith at the University Hospital, Ann Arbor, Michigan. The present material is obtained from the first 102 cases of a total series of 612. They have been observed over a period of three years, and the results are recorded in three consecutive papers.[1] The study mainly concerns the "non-articular" aspect of so-called atrophic arthritis on the generally accepted principle that the joint changes are only a manifestation of a profound physiological disturbance involving the autonomic nervous system, the vascular system, and the smooth musculature. Millard Smith begins with a classification of arthropathies. It seems unfortunate that we should be burdened with yet another classification but, as he says, nearly every writer uses a different nomenclature and it is essential that he should make it clear which he has adopted. The first or introductory paper proceeds along the following lines: distribution of cases by sex, incidence by age-groups, habitus, complexion, occupation and social status, distribution of sub-types of atrophic arthritis at the onset of the disease and when last seen, with a further study of the changes in the type of the arthritis at the onset and when finally observed; it ends with a study of the blood and the basal metabolism. Much of this has been done before, and nothing strikingly different from previous observations emerges; its value lies chiefly in confirming views already held. The second paper deals with constitutional defects. Millard Smith points out how unfortunate it is that the theory of focal infection has blinded observers to physiological deviations from the normal and consequently the constitutional aspect of the disease. He emphasises R. L. Jones's accurate clinical account of the condition by reporting similar findings in this group of 102 cases, thereby paving the way to a more liberal theory of the disease than that based on the limited one of joint infection. He lays stress especially on the regular prodromal period and its constitutional signs, which prevail and become exacerbated in the arthritic stage. He finds the disease has strong familial tendencies and the data on the allergic traits suggest an abnormal reactibility common to a significant number of patients. Allergic manifestations are evidence of a peculiar reactibility on the part of the autonomic nervous system, the vascular system, the smooth muscle system, and Millard Smith demonstrates by a study of the prodromal symptoms and signs and the constitutional symptoms and signs after the disease has become arthritic, that it is these very systems that appear, strikingly enough, to be involved. The difference is that in the allergic state there is an autonomic imbalance in favour of the parasympathetic division, and in atrophic arthritis an imbalance in favour of the sympathetic division. Since the two states are incompatible in the same tissue at a given time an explanation is forthcoming for the reciprocal relation of allergy to the disease. He concludes his second paper by saying that atrophic arthritis should be thought of as a neurovascular disease and certainly not as an infectious arthritis. The third and last paper is devoted to ætiology. It is shown that physical and emotional trauma occurs with sufficient frequency in these cases to be considered seriously as having an ætiological rôle. Even in connexion with so-called menopausal arthritis it appears that focal infection and emotional and physical trauma play an important part.

[1] New Eng. Jour. Med., 1932, ccvi., 103, 160, 211.

These three papers should certainly fulfil their object—namely, to add momentum to an increasing interest in "non-articular" aspects of atrophic arthritis.

EXPERIMENTAL RENAL FAILURE

THE physician interested in nephritis has long been confronted with a problem of great importance. Can the rise of blood pressure observed in many cases of Bright's disease be properly considered secondary to the renal lesion; or is it not rather evidence that the renal vessels have undergone severe change parallel with independent change in others of the smaller blood-vessels? Should not arterial hypertension be interpreted as a sign that the renal lesion is secondary to a vascular defect?

The first important work on this problem was the classical series of experiments by Sir John Rose Bradford in 1899. He showed that removal of two-thirds of the total kidney tissue in animals caused polyuria, and that removal of three-quarters of it caused polyuria with an increase in the total urea excretion, but with nitrogen retention; cardiac hypertrophy was not produced. Subsequent investigations have often given conflicting results; thus Janeway, Cash, and others claimed to have produced some degree of arterial hypertension by various methods of partial renal destruction, whereas Anderson and others failed to get such effects. In view of this conflict of evidence it is of interest to read of a study by A. Chanutin and E. B. Ferris,[1] who have carried out some careful experiments, with ample controls, on rats. Their method was to remove half to three-quarters of one kidney, and, after a week's interval, the whole of the other kidney. The usual laboratory methods for examining the blood and urine were employed and the diet was elaborately regulated. Estimation of blood pressure proved difficult, and finally the observers were obliged to have recourse to direct estimation of the pressure by introducing a cannula into the carotid artery just before killing the animal. Large numbers of control animals were employed so as to determine the constancy or otherwise of apparent deviations in the experimental animals. Definite nitrogen retention and pronounced polyuria were observed during the first few days after completion of the operative measures, but the volume of urine diminished within a fortnight. After this time the degree of nitrogen retention and polyuria were found to depend on the extent of renal damage. Animals killed at intervals were found to show renal hypertrophy after the second week; hypertension in this early stage was noted in only one case and probably cannot be considered significant. The observations were then carried out on a large group of animals in apparently good health at a period of more than six weeks after completion of the operations on the kidney; all animals with pulmonary disease and anæmia were excluded from the series. It was found that retention of 50 to 197 mg. of non-protein nitrogen was present. In all cases where renal insufficiency was marked there was a notable elevation of the blood pressure, although this could not be shown to run strictly parallel in all cases to the degree of renal failure; in other words the degree of nitrogen retention could not be used as a criterion for the prediction of hypertension. Definite thickening of the left ventricle was often present. A special study was made of a group of partially nephrectomised animals, which had moderate anæmia although their health seemed otherwise good. The renal damage in these cases was shown to produce polyuria with urine of a constant low specific gravity. A few of these rats showed no hypertension and in the rest there was again no close relation between the degree of hypertension and of nitrogen retention. All animals which were in any way severely ill were excluded when reaching these conclusions.

Commenting on these findings Chanutin and Ferris say that they think the polyuria depended to a great extent on the hypertension, and are inclined to support the postulate of Verney that such hypertension represents a protective mechanism designed to increase the work of the residual glomeruli. Amongst the negative findings in this series of observations it should be noted that œdema was never produced.

PSYCHOLOGICAL FACTORS IN PERIPHERAL VISION[1]

A PIECE of research designed to investigate the physiological and psychological components in peripheral vision has important bearings on everyday problems. Central rather than retinal processes were investigated, the method being the exposure of many different figures by a specially designed tachistoscopic apparatus which allowed for the perception on the periphery of the field at various meridians. The results showed that perceptual accuracy diminished with increase of eccentric angle of exposure of the forms. Larger forms are more easily perceived than smaller ones. Increased eccentric exposure makes objects appear less bright and smaller under the experimental conditions. Reports are influenced by past experiences of the observer in the experimental procedure. Time exposure increases accuracy in recognition, and simultaneous exposure of other objects in other fields diminishes accuracy. There is also a tendency to under-estimate the eccentric angle of exposure and this effect persists even when the form is exposed near a fixed and continuously illuminated reference mark. It is found difficult to separate physical, retinal, and central components.

The inquiry is really an extension of work done on retinal stimulation in eels by Adrian and Matthews, who found that retinal excitation in one area led to a reinforcement of action and of excitation in another. In some of these human experiments, however, mutual inhibition was found to occur when two fields were simultaneously excited. Myers Salaman's observation, as is here recalled, showed that both inhibition and reinforcement took place. The most likely explanation is the existence of two levels of activity in perception—a retinal excitatory and a central inhibitory process.

THE RE-ALLOCATION OF RADIUM

CHANGES in the distribution of the 10 grammes of radium acquired by the King Edward's Hospital Fund for London are recorded in the report of their distribution committee, which was presented at the annual meeting on June 7th. In the course of 1931 the authorities of St. Mark's Hospital for Diseases of the Rectum found that the number of their cases suitable for treatment with radium had decreased, and were therefore able to return the 100 mg. lent them by the Fund. Pending re-allocation this radium has been in temporary use at other hospitals. In June, 1931, the Westminster Hospital submitted a report by its radium staff which described the results obtained by the use of the 4-gramme bomb as being so discouraging as not to justify the hospital in financing the undertaking further. This bomb had been acquired by the Fund in exchange for an equal quantity of radium to be used by the National Radium Commission outside London, part of the arrangement with the Commission being that the hospital should continue the scheme of radium therapy agreed between the hospital and the Commission. The King's Fund interviewed the representatives of the hospital, and ascertained that the Commission, having considered the hospital's report of the results of the use of the bomb, were unanimous in recommending its division into four units of 1 g. each, to be allocated to separate hospitals for surface therapy. After many discussions and conferences, the recommendation of the Commission was accepted in principle by the distribution committee, and the four 1-gramme units were allocated one each to the Cancer (Free), the Middlesex, University College, and Westminster Hospitals, and the 100 mg. returned by St. Mark's to Guy's Hospital.

TREATMENT OF PARKINSONISM BY TRYPAN-BLUE

A FEW years ago three French workers reported definite improvement in one case and doubtful results in two others from the use of trypan-blue in the treatment of the parkinsonian sequelæ of encephalitis lethargica. Laignel-Lavastine and Jean Sterne [1] have now used this remedy in 15 cases which had not benefited appreciably by the ordinary measures. They state that none but the purest trypan-blue is of any value; as it is accumulated and not eliminated, it must be given in weak doses well spaced out, but it maintains its action. They claim that its action is more than symptomatic. They use a 1 per cent. solution in water and the course is as follows: two injections of 1 c.cm. each, followed by three or four injections of 2 c.cm., the interval between each two injections being three or four days. An interval of a month is allowed between courses. The solution is injected intravenously, but no harm is done if any of it is accidentally injected into the tissues. There is usually a slight reaction with vasodilatation in the face, cough, slight tachycardia and rise of blood pressure, and an accentuation of tremor; this lasts for a few minutes and is succeeded by a short period of vasoconstriction, after which the patient returns to a normal condition. No ill-effects of any kind have been observed, and the injections have been well tolerated even by very exhausted patients. The authors stop when they observe a bluish tinge of the conjunctiva and integument; they do not agree that this colour goes side by side with the therapeutic effect. A transitory improvement is sometimes observed after a few injections. Sometimes permanent improvement makes its appearance early; sometimes it is tardy; in one case the treatment was continued for two years—largely to please the patient—and the improvement took place suddenly. Recent cases are found to be more susceptible to treatment than advanced ones, but even the latter sometimes give good results. The symptom which seems to be most affected is the muscular rigidity; one patient who could only swallow liquid was able to take bread, and another was able to recommence wood-carving. In the best cases there is a great diminution in neurological signs. The tremor is much less influenced, but it is sometimes possible to reduce or even to dispense with scopolamine. The eye symptoms apparently do not improve, but the mental dullness is reduced. In the evolutionary forms with somnolence, clonic spasm, and loss of control over salivation, Laignel-Lavastine and Sterne claim a diminution in the symptoms.

DR. Robert J. Rowlette has been elected president of the Irish Medical Association.

WE regret to announce the death of Prof. Leith Murray, professor of obstetrics and gynæcology in the University of Liverpool, which occurred on Saturday last, June 11th, in the 53rd year of his age. His sudden death is a loss not only to the City and University of Liverpool, but to a very wide circle of friends.

THE annual elections at the Royal College of Surgeons in Ireland were held last week. Mr. Frank Chetwode Crawley, vice-president, was elected president, and Mr. Seton Pringle, vice-president. Mr. Crawley is ophthalmic surgeon to the Royal City of Dublin Hospital, and one of the surgeons to the Royal Victoria Eye and Ear Hospital. Mr. Pringle is surgeon to the Royal City of Dublin Hospital and to Drumcondra Hospital.

BRITISH MEDICAL ASSOCIATION: MIDDLEMORE PRIZE, 1933.—The Middlemore prize, consisting of a cheque for £50 and an illuminated certificate, and founded in 1880 by the late Mr. Richard Middlemore, of Birmingham, is awarded annually for the best essay or work on any subject which the council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The council of the Association will consider an award of the prize in the year 1933 to the author of the best essay on the treatment of glaucoma. Essays must reach the Medical Secretary, B.M.A. House, Tavistock-square, London, W.C.1, on or before Dec. 31st, 1932, signed with a motto only and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author.

A Voyage d'Études Médicales to the watering-places of France will take place this year in Central France from Sept. 8th to 19th inclusive, under the conduct of Prof. Maurice Villaret and Dr. Etienne Chabrol. The party will assemble on Sept. 8th at Pougues. The principal places to be visited are St. Honoré-les-Bains, Néris-les-Bains, La Bourboule, Mont Dore, St. Nectaire, Royat, Châtel-Guyon, Vichy. Further information may be had from Madame Juppé-Blaise, Federation of the Health Resorts of France, Tavistock House (North), Tavistock-square, London, W.C.1.

WHAT IS WRONG WITH THE MEDICAL CURRICULUM?

(A Series of Opinions Contributed by Request)

II

BY RALPH M. F. PICKEN, M.B., B.Sc., D.P.H.
MEDICAL OFFICER OF HEALTH FOR CARDIFF; LECTURER IN PUBLIC HEALTH AT THE WELSH NATIONAL SCHOOL OF MEDICINE

ALTHOUGH I am assuming that any criticism of mine of the medical curriculum will be of interest mainly in relation to the teaching of preventive medicine, I cannot refrain from mentioning that certain general features of the output of the medical schools are inevitably impressed upon the minds of those who, like myself, are passing through their hands a considerable number of post-graduate students and assistant medical officers. Personally, I am not very much concerned as to whether the men and women who come on to my staff have a great deal of knowledge. As a matter of fact, they have often an astonishing accumulation of smatterings of information. But, when that information relates to my own special line of work, I find that much of it is already obsolete, and I conjecture that the same is true of some of the items of information they have collected about other branches of medicine. On the technical and manipulative side they appear to be quite good, and it seems to me to be right that the schools should concentrate upon making them so; for it is hard to acquire technique from the study of literature in the isolation of post-graduate practice. But the other things which they ought to have acquired—initiative, resourcefulness and, above all, capacity to go on learning and unlearning—I find singularly lacking, and I do not admit that such things cannot be taught. Especially in our branch of medicine, where the temptation to make pronouncements is great, scientific scepticism and a suspension of judgment which is not mere hedging are much to be desired. It is hard to compare immeasurables of the present with the past, but my impression is that deficiency in these respects is at least as great now as it was when I graduated and perhaps greater than in the student days of my teachers. Probably the much better organisation of medical teaching nowadays is offset by the admitted overloading of the curriculum.

I note with some concern that there are still medical men who worship at the shrine of the "single portal," which would force all our teaching into moulds created by anonymous examiners and still further encourage the mental accumulation of facts. I do not wish to see any reform of the curriculum which would magnify the importance of ordeal by examination. Although I have a profound faith in the future of preventive medicine, I do not desire to be a party to any further burdening of the student mind with specialised knowledge of my own kind. But as we have found no practical substitute for the examination system we should at least try to make it more reasonable and effective.

A REVOLUTION IN OUTLOOK

Apart from these general considerations, we of the public health service are interested in the teaching of medicine in all its branches because successful public health work entails familiarity with many aspects of medicine and of medical practice and outlook which cannot be described strictly as preventive. While it is desirable that public health officers should be administrators with a scientific bent, it is also essential that those whose daily work includes the care of patients in council hospitals of various kinds or the holding of out-patient consultations under school medical, maternity, child-welfare, tuberculosis, or venereal diseases schemes, should be sound clinicians. The public health official is a practitioner of medicine, practising his art sometimes directly upon his patients, sometimes on the public in groups. His success depends on many things, but always, in the last instance, upon his knowledge of medicine. His peculiar interest should be to get behind the manifestations of diseases to its origins, to watch for the weakest link in the chain of causes and to lead the attack upon it. He finds himself in agreement both with the layman's view that prevention should take the place of cure, and with the contention of his professional colleagues that preventive and curative medicine cannot be separated from one another; but he thinks that medical teaching and medical practice still tend to lay all the stress upon cure, and that almost a revolution in the outlook of some of the teaching bodies will be required before there is prospect of the young graduate fledging with a conception of the paramount importance of prevention even as clear as the average man in the street has.

The practitioner of preventive medicine is not blind to the fact that there is a very good reason why the teachers of medicine, surgery, and obstetrics who have the students in their final years, tend to be perfunctory in their references to prevention. He knows that the practical demand upon the medical profession is mainly for treatment and that even within the public health departments this demand has to be met. Moreover, the clinical manifestations of a particular disease affecting an individual are even now, though much less than formerly, such that one mind can apprehend them and control the application of the appropriate remedies. On the other hand, public health measures have been, even more in the past than now, questions of large scale organisation, like the provision of isolation hospitals, or engineering works, such as the installation of waterworks or schemes of sewage disposal or the ventilation of public buildings. Naturally, the teacher of medicine has dismissed such matters with a casual reference, as being fortunately outside the province of the average medical man or woman. So that the curriculum which starts, rightly I believe, by inculcating a scientific outlook with a bias toward the natural sciences, then proceeds to make fairly ample provision for studies of the normal working of the healthy human body, of pathological processes and the causative elements of diseases, concentrates in its later years upon the treatment of disease and the application to it of the already acquired knowledge of physiology and pathology, to the almost complete exclusion of the bearings of these sciences upon prevention. Moreover, organised public health effort calls to its aid mathematical methods and the exact sciences to a much greater extent than ordinary medical practice does, and the teachers of medicine are not greatly concerned with these things which they and the senior students consider they have left well behind them. Preventive medicine of this kind is not a subject which the average teacher of medicine could be expected to deal with.

COURSES IN HYGIENE AND FEVERS

In recognition of this aspect of the problem most teaching bodies have worked into their curriculum, at some stage convenient to the teachers of other subjects, a short course under the title hygiene or public health or preventive medicine, but until comparatively recently such courses were perfunctorily conceived and designed. They tended rather to emphasise the exclusiveness of this province of medicine, which was apt to mean "drains" to the undergraduate as "stinks" were chemistry to the schoolboy nourished upon classics. It is unnecessary to discuss at any length such courses, their defects and their reform, for the matter has been covered by a recent comprehensive report of the Society of Medical Officers of Health[1] which has been sent to the General Medical Council and the various teaching bodies for their consideration. The society have drafted a model syllabus which aims at recognising the importance of confining specific teaching on public health to those aspects of it which will be useful to the non-specialist practitioner and about which he is otherwise unlikely to be informed. At best such a syllabus can cover the ground only of a very much modified and abbreviated D.P.H. course. It includes a variety of necessarily disconnected items whose collective significance is not readily grasped except by those who are nearing the end of their undergraduate period and contemplating the problems of actual practice. It should therefore be placed near the end of the curriculum. In fact, the course in public health is apt to be squeezed out of the final years, yielding place to studies of a more clinical nature. For the reasons already given, it is not surprising that hygiene should get left in the scramble for a place in the final year's scheme of studies.

Again, when we contemplate the evolution of medical treatment and medical teaching, it is a matter of no surprise that instruction in "fevers," such as it is, is regarded purely as a part of systematic and clinical medicine, and is therefore apt to be wrongly related to the study of public health which is so largely concerned with the control of communicable disease. But it is disconcerting to find that the lecturer or clinical teacher in fevers may have students in his class who have had little or no opportunity of learning about even the clinical manifestations and treatment of complications of the fevers about which he ought not to have to teach them. Finally, a question may or may not be set in the paper in medicine, but if it is set, the answer is probably scrutinised by examiners who practically never see fevers and who probably have quite vague ideas as to the nature of the teaching. In the provincial schools, at least, the teachers of hygiene and fevers are usually closely associated with one another in the local health department. Their point of view is, or ought to be, similar and the examination in fevers, both written and clinical, would fit much more aptly with that of hygiene than medicine.

It is suggested therefore that the courses of instruction and the examinations in hygiene and fevers should be brought into association with one another and that they should together be given a place in the curriculum commensurate with their practical importance to the practitioner of medicine.

THE PROPHYLACTIC SPIRIT

This claim, however, represents a very minor part of our plea for the place of preventive medicine in the curriculum. Indeed, it is almost borrowing a *cliché* to say that preventive medicine should permeate the whole curriculum. How it may be done has been set out by Sir George Newman in his "Recent Advances in Medical Education in England" (1923). The report of the Society of Medical Officers of Health, already referred to, puts it this way, "Adequate training in preventive medicine can never be given in any *ad hoc* course of instruction; it can be secured only with the active co-operation of all teachers of the medical school." We must, of course, be prepared to answer the request for a plain statement as to what the teachers are to do. The answer is, indeed, perfectly simple. It is that every teacher of medicine, surgery, and obstetrics will give as prominent a place to the practical means of prevention of each disease, so far as they are known, as he does to its clinical manifestations and treatment. It means, of course, that teachers must be as greatly interested in prevention and as up to date in their knowledge of it, including its practical difficulties, as in diagnosis and treatment. In fact, their occasional pronouncements on the subject are frequently unpractical and quite often scientifically unsound. The impression of public health officers is that most of them are neither interested nor well-informed, and it is hard to see how their interest is to be roused. This is the real difficulty. My own experience as an undergraduate convinces me that it is not insuperable, for I happened to have teachers imbued with the prophylactic spirit. From comparatively early times there had been a close association between the public health administration of Glasgow and its medical school. Sir William Gairdner for a time combined the duties of professor of medicine and medical officer of health. The professors of medicine and surgery of my own time had been resident medical officers in the great fever hospitals of Glasgow, and, indeed, it was quite in the ordinary and direct line toward consulting practice to seek such posts. In this way successive generations of teachers came under the influence of distinguished hygienists like J. B. Russell, A. K. Chalmers, and John Brownlee. Prof. Samson Gemmell, when he was a young physician, used to spend his evenings prowling round the slums with J. B. Russell, and his caustic comments on the family circumstances related on the bed-cards ("thirty shillings a week and the fecundity of rabbits!") left an indelible impression of the importance of social factors upon the minds of his students. Macewen, too, never ceased to hark back to the causes of surgical diseases and to emphasise the practical measures by which they might be prevented. I gather from my colleagues that some of the schools, especially those which have not been associated so closely with university and town life, have not exhibited this preventive bent, and I think I notice the difference both in the proportion and quality of the men and women entering the public health service from such schools and also in the lack of interest in preventive medicine, and the narrower social outlook, of those who enter private practice.

A HOPEFUL SIGN

It is perhaps a hopeful sign that we have seen in recent years men who have made a great name for themselves in medicine or surgery retiring into a life of public health publicity. It is true that these men, who have been clinical teachers of note, sometimes exhibit more goodwill than understanding of the practical problems of prevention. But the spirit is there, and, if the viewpoint they have reached has its influence upon those who have sat at their feet as clinicians, we may move much more rapidly to the right sort of teaching in preventive medicine than most of us dare to hope. It is possible also that the growing use for teaching of the hospitals under the management of the health departments may help in this direction, because it is reasonable to suppose that there will be in future a tendency toward freer circulation of staff as between the preventive and curative divisions within these departments.

---

[1] Public Health, 1930, xliii., 253.

But, however they are to be attained, there should be no misunderstsnding as to the aims of the public health service in relation to the medical curriculum. We certainly want the special courses on hygiene or public health or preventive medicine, or whatever it may be called, and on fevers, to be good courses and to be fitted into their proper places in the schemes of study. But we are still more concerned that the prevention of disease should never for one moment be lost sight of throughout the whole curriculum.

ACUTE POLIOMYELITIS IN CLINICAL PRACTICE

By G. R. Girdlestone, M.B. Oxf., F.R.C.S. Eng.

HON. SURGEON TO THE WINGFIELD ORTHOPÆDIC HOSPITAL, AND HON. ORTHOPÆDIC SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD

The diagnosis and treatment of infantile paralysis is of intense interest nowadays, apparently for two reasons: first, the warning of epidemics which have been occurring on a small scale in our country and on a large scale in the Dominions; and secondly, the almost magical advance that has been made in treatment. The paper by Macnamara and Morgan,[1] recently published in this journal, gives convincing statistics as to the possibilities of preparalytic diagnosis and the effects of treatment by convalescent serum, and also outlines the indications for orthopædic treatment.

In this country it has not been thought possible—at any rate in the absence of an epidemic—to make a preparalytic diagnosis, and, further, efforts towards diagnosis at this stage have not seemed necessary because the effect of serum treatment has hitherto appeared to be rather problematical. Also the value and the urgency of orthopædic treatment is not yet fully appreciated or widely recognised.

I try in this paper to give due balance to the treatment indicated at various stages, and to the preparatory steps that we, in England, must take forthwith. Who can say when a big epidemic may visit us? Danger lies in inaction based on what may well be a false sense of security. Various small epidemics have occurred in this country in the last five years, and what happens on a small scale can, and probably will, happen on a large scale. Though the epidemics have been small they are none the less significant, and, whether we are to suffer from big epidemics or not, a high proportion of our sporadic cases are of the epidemic (acute febrile) character, and therefore susceptible of preparalytic diagnosis.

No longer can we plead ignorance of the symptomatology of the prodromal stages or of the *spinal sign* which is a specific and timely warning of involvement of the central nervous system; timely in that it appears sufficiently long before the toxins reach the anterior horn cells to give us time to act *if all is ready to hand.*

THREE STAGES

From the point of view of treatment the disease may be considered in three stages, and I propose to give a clinical example of each stage.

Case 1.—One day in September, 1926, a doctor found that his son, aged 6, was seriously ill. His temperature was up to 105°F., he had severe headache, and within 24 hours severe retching and vomiting which lasted two days. There was nasal catarrh with thick mucous discharge, said not to be membranous. His throat was not examined. Headache and pain in the neck and back persisted three or four days. There was no coma, he was slightly delirious at night, but perfectly lucid in the day. On the fourth day he complained of general weakness, could not move his limbs, and could not move about in bed. Within 24 hours he became almost completely paralysed, except for diaphragmatic breathing, and talking made him short of breath.

On the third day of the boy's illness, his mother sickened and went day by day through an almost identical illness. First fever, then within 12 or 24 hours severe headache, later persistent retching and vomiting. The vomiting was exceedingly diffic[illegible] and only a little greenish mucous was [illegible] up. There was very severe nasal catarrh with thick mucous discharge, said to be non-membranous. The throat was not examined. Her temperature reached, but did not exceed, 104°F. On the fourth day she complained of her neck and back. On the sixth day she began to feel all her muscular power leaving her, and became paralysed in all four limbs and trunk. She complained bitterly of difficulty in breathing, the auxiliary muscles of respiration were paralysed, the platysma remaining active.

The patient was eight months pregnant, and early on the fifth morning labour commenced and the baby was born without difficulty, and fortunately remained quite well.

Here indeed was a tragedy, for both patients were extensively paralysed. To have saved both mother and son a preparalytic diagnosis on signs and symptoms alone would have been necessary, and there was no epidemic to give a timely hint. But for the mother the diagnosis was ready-made. Lumbar puncture for confirmation and immediate injection of convalescent serum would have given her immunity.

Case 2.—On Sept. 19th, 1922, a small boy was sent over to the Wingfield Hospital from Banbury, on about the 14th day of acute infantile paralysis. He had been, and was, ill, crying, restless, fretful, peevish, sleepless. He was wrapped in smooth-surfaced cotton-wool bandages and put on a softly padded spinal frame with head-piece, and within an hour or two all his distress disappeared and he became passive, content, and placid, an entirely different child.

When one considers the life of the average anterior horn ganglion cell, the reason for this dramatic change is obvious. Each such cell is normally compelled to allow its body to constitute a sort of telephone exhange by which various cells can make connexion with the muscle-fibres (200 or more) for which it is responsible. On the reflex side the muscle is rung up from skin, joints, and other parts of the sensorium, and the frequency of all these rings depends upon the movements of the part concerned. The messages to the motor-end-plate through the reflex arc emanate from the anterior horn cell at about eleven per second. Then on the voluntary side the cortical cells ring up the muscle whenever movements are required, and their messages pass from the ganglion cell at some 30 to 50 per second. The anterior horn cell is undisturbed only when its owner is completely at rest or asleep. During the first few days of anterior poliomyelitis not only are these cells inflamed and poisoned by the virus, but their owner is restless, fretful, and sleepless. The aching cell is subjected to, and doubtless maddened by a constant succession of cortical and reflex stimuli. Now note the change. The smooth wool covering and the complete relaxation produced, and indeed enforced, by comfortable splintage, cut out both reflex and cortical stimuli, and the ganglion cell is at rest. Clearly the chances of recovery of every such cell are immensely enhanced.

[1] The Lancet, Feb. 27th, p. 469, March 5th, pp. 520 and 527.

CASE 3.—On Jan. 29th, 1931, a girl, aged 13, was brought to see me at one of our clinics. Her face was impassive and gloomy. Only two positions were possible to her: (1) she could lie on her side, completely doubled up, with her hips against her abdomen; or (2) sit in the most extraordinary position, her thighs, legs, and feet flat on the table, and her whole abdomen and chest resting along her thighs, with her face only a few inches above her feet. This was on account of fixed deformities, due to complete lack of any sort of orthopædic control.

Some years previously this girl was attacked by infantile paralysis within a few miles of the orthopædic clinic to which she only now for the first time had been sent.

WHAT SHOULD BE DONE

These cases illustrate the three main stages of the disease relative to its treatment, and from these illustrations it is easy to extract certain indications for action. But incidentally it is worth mentioning that those instances are not rare exceptions. In the three counties of Berkshire, Buckinghamshire, and Oxfordshire, with a total population of about 750,000, I have been responsible during the past nine years for the treatment (almost always at a late stage) of some 650 cases of anterior poliomyelitis which has left residual paralysis.

The indications for action may be summarised as follows:—

1. The widespread distribution of a description of the signs and symptoms of infantile paralysis in its preparalytic stage, so that every practitioner may be on his guard for the febrile case, whether sporadic or epidemic, and particularly understand how to recognise poliomyelitis arising in a "contact." At the same time he must realise how urgent is the (one) lumbar puncture to confirm the diagnosis and to administer convalescent serum. Dr. Macnamara compares this urgency to that of operation for an ectopic gestation.

2. The practitioner is helpless unless some one in his district is prepared to make a microscopic examination of the cerebro-spinal fluid at the bedside, and has been previously supplied with convalescent serum. Dr. Macnamara's figures, which are supremely convincing, come from the use of convalescent human serum put up in sterile ampoules without antiseptic, and her arguments for the avoidance of any irritating factor in the serum to be introduced into the theca are very strong, for intrathecal irritation masks the effect of the serum and makes it hard to assess the need for a further dose. I would suggest therefore that, without delay, arrangements should be made for the collection, pooling, preparation, testing, and distribution of convalescent serum throughout the country, and this distribution, while it must be widespread, should be confined to medical men whose attainments in clinical pathology are undoubted.

3. Organisation is necessary to ensure that any case in which paralysis has occurred is immediately put under orthopædic care.

For the effective working of these three phases of action the approval and coöperation of the Ministry of Health is essential.

In the State of Victoria the Poliomyelitis Committee has issued a pamphlet on behalf of the Government and the metropolitan municipalities. This pamphlet, I think, deserves study in this country, and the substance of it is reproduced below.

A MEMORANDUM ON POLIOMYELITIS

Poliomyelitis is an acute specific infectious disease which occurs sporadically and in epidemics. The infection is probably spread by means of the nasopharyngeal secretions of affected persons or carriers, though bowel discharges may also convey infection. In a few instances localised outbreaks have been traced to infected milk supplies. The virus usually enters the body by way of the nasopharynx, invades the blood stream, causing a systemic infection, and in the majority of cases recovery then ensues—abortive cases. In a proportion of cases, however, after an interval, the central nervous system is invaded and, as a result of interference with the vascular supply by leucocytic aggregation around the vessels of the brain and cord, destruction of some of the cells results. The extent of paralysis which results depends upon the degree of interference with the blood-supply to the anterior nerve-cells. The incubation period is usually five to eight days.

Symptomatology

MODE OF ONSET

In earlier epidemics a number of cases occurred in which the onset of paralysis followed very closely upon the onset of the illness. Fortunately in the epidemics of the last decade this type of case is rare. The majority give a definite history of illness extending over several days with or without an intermission. Draper classifies the mode of onset as follows:—

1. *Fulminating.*—Hyperacute cases in whom paralysis is not preceded by illness. These are uncommon.
2. *Dromedary type.*—In this group, after a period of symptoms of general infection, an interval of apparent recovery precedes the signs of meningeal invasion which usher in paralysis. This type has been common in Victoria in the last five years.
3. *Straggling group.*—In these, slight variation occurs in the symptom complex of a sustained and progressive illness.

GENERAL SYMPTOMS

Fever is usually present, rarely high, and in adults the temperature may not be higher than 99° F. It varies in different localities and at the various seasonal phases of an epidemic. Headache is common and frequently severe. Constipation has been usual. Convulsions are uncommon, repeated convulsions so rare that their occurrence would suggest another diagnosis. Vomiting once has been the rule and in young adults it may be persistent. Symptoms of involvement of respiratory and gastro-intestinal tracts may occur and the complaint of sore throat has been frequent. The tonsils are usually engorged. Such symptoms may occur with any of the acute infections, but, even at this stage, there are certain signs which aid in the differentiation from other diseases. Drowsiness and irritability occur in the same patient, the child lying quietly and apathetically unless disturbed when he becomes apprehensive and resentful. Retention of urine and localised or generalised sweating may occur at this stage.

Fever, vomiting, headache, constipation, drowsiness, and irritability and sweating, and possibly retention are enough to justify a tentative diagnosis of poliomyelitis and, in times of epidemic at least, demand careful observation for the first evidence of meningeal involvement if such is to develop.

STAGE OF MENINGEAL INVASION

Pain may be felt in the back, in the neck, in the limbs and between the shoulders. In older patients it is severe, and in all, aggravated by anterior flexion. True head retraction and opisthotonus may occur as definitely as in tetanus and cerebro-spinal meningitis, but more usually the *spine sign* is present. This sign may be described as a disinclination to flex the spine anteriorly because "it hurts." Most children, if handled patiently, will try to obey when asked to kiss the knees, but if the spine sign be present the attempt is given up because of the pain induced by anterior flexion. *Amoss's sign* is a modification of the spine sign, and it is useful with older children. When placed sitting upon a chair or table and asked to fold the arms the child may attempt to do so, but quickly reverts to the position in which part of the body-weight is borne through the arms, which make two legs of a tripod, the spine being the third. In babies one has to rely on passive flexion to estimate the degree of pain caused by the movement. Popliteal pain is common and may be persistent. Hyperæsthesia may be generalised or local, and it is unaccompanied by swelling. Tremor of the hands is frequently observed. The reflexes are irregular, inequality is common and an increase in the irritative stage is usually followed by loss when the paralysis occurs. Even in the absence of an epidemic the presence of some of these signs, hyperæsthesia, tremor, spine sign and Amoss's sign, pain in the neck, retention, following a general infection as evidenced by some fever, headache, &c., justifies the presumptive diagnosis of poliomyelitis and calls for proof by examination of the cerebro-spinal fluid.

It cannot be too strongly emphasised that lumbar puncture in acute illness, in the absence of definite indication, is unreasonable and unfair, but in times of epidemic of poliomyelitis every instance of illness in which a careful physical examination cannot reveal the cause should be watched carefully for the first evidence of meningeal invasion and, if the signs appear, a lumbar puncture should be carried out forthwith. It is only justified, however, if provision is made for immediate bedside examination of the cerebro-spinal fluid and if immune serum is available. It has been shown to be dangerous to remove a quantity of fluid from a case of poliomyelitis in the preparalytic stage and to delay the administration of serum while that fluid is sent away for examination. For diagnostic purposes 5 c.cm. of cerebro-spinal fluid suffice, and the examination at the bedside can be carried out quickly if the microscope and counting chamber, &c., are ready for use before the lumbar puncture needle is inserted. By this means a second lumbar puncture may be avoided if one desires to give serum intrathecally.

In cases of poliomyelitis the pressure is usually increased, and the fluid is clear or, at most, "ground glass" in appearance. Globulin is slightly increased, but frequently twenty minutes must elapse before reading the ammonium sulphate test. The cells are increased, polymorphonuclear and mononuclear, the ratio of the latter increasing rapidly as paralysis approaches. The chlorides are not reduced, thus furnishing a useful means of differentiation from tuberculous meningitis, which clinically resembles poliomyelitis and in which the cerebro-spinal fluid also shows a pleocytosis. The apparatus for estimation of the chlorides is very simple and the test easy and reliable.

STAGE OF PARALYSIS

It is usual to classify paralysis as follows :—

1. Spinal—affecting the lower motor neurone, the common type.
2. Cerebral—affecting the upper motor neurone, causing a spastic paralysis.
3. Cerebellar—in which ataxia is a predominant symptom.
4. Polyneuritic—in which hyperæsthesia is marked. Anæsthesia is uncommon and if persistent suggests a diagnosis other than poliomyelitis.
5. Bulbar.
6. Ascending cases in which the paralysis spreads upwards.

In epidemics earlier in this century the initial paralysis was usually not exceeded, but in the last few years the tendency to spread over several days and even to extend some weeks later has been observed in Victoria and Tasmania. In all cases the ultimate residual paralysis is less than the initial. The recovery of muscle function, which results in any case, depends upon two factors, firstly, upon number of new cells which survive, as the subsidence of the leucocytic aggregation and œdema around the vessels re-establishes the circulation ; and, secondly, upon the care given to the patient, especially during the first two years.

In cases in which respiration is interfered with the drowsiness of the early stage changes to an alertness, all energies being concentrated upon the effort of breathing. The flaccidity and asymmetric distribution of the paralysis have been dealt with fully in the older literature. Bulbar-spinal types with ocular and facial paralyses are characterised by a profound stupor, but the prognosis for life is better than in the alert children. Mortality in poliomyelitis is not due to toxæmia but to interference with respiration.

Treatment

BY HUMAN IMMUNE SERUM

The prodromal symptoms have been emphasised because the recognition of the disease at this stage is essential for successful treatment by means of serum prepared from the blood of persons who have survived an attack of poliomyelitis.

Immune serum has been prepared for the Committee by the Commonwealth Serum Laboratories, Melbourne. No antiseptic has been added, but the sterility of the serum has been very carefully ensured. The serum is stored in 10 c.cm. ampoules. In order that the method of therapy shall not be brought into disrepute by use in unsuitable cases or by unsatisfactory technique, the committee has arranged for various depôts throughout the country where the serum is held at ice-box temperature in charge of a consultant prepared to carry out the necessary examination of the cerebro-spinal fluid and to direct the administration of the serum.

Serum should be administered intrathecally and intravenously, the dosage usually averaging about 60 c.cm. A second intravenous dose or even a third may be necessary if the response to the first is not immediate. The intrathecal injection should be given slowly and by the gravity method, after withdrawal of a larger amount of cerebro-spinal fluid. When the serum has been used under conditions regarded as essential : (1) without delay between withdrawal of fluid and its administration ; and (2) when given intrathecally and intravenously in adequate dosage, the results of the therapy in Victoria have been in line with those of workers in America and New Zealand, summed up by Aycock as "beneficial as evidenced by (1) a low mortality-rate ; (2) a low average total paralysis ; and (3) a strikingly low proportion of paralysis of the severer grades."

The recognition of the preparalytic stage is essential for successful serum therapy. Administration within 24 hours of the advent of paralysis is justified if the patient is febrile and the supply of serum ample. If given later, when paralysis is stationary, serum is of no value ; while in the spreading cases administration is justified, but is sometimes unavailing.

TREATMENT AFTER THE ADVENT OF PARALYSIS

Lovett has divided the treatment after paralysis has occurred into three phases :—

(*a*) The acute stage—lasting until the disappearance of the tenderness.

(*b*) The convalescent stage—from the end of the acute stage and continuing as long as recovery is occurring—lasting over two years.

(*c*) The chronic stage—when the condition is more or less stationary.

In the acute stage rest should be as complete as possible and nursing disturbance reduced to a minimum. The patient should be nursed on a firm bed, and the limbs kept in position from the onset, by means of plaster beds or improvised splints, to prevent stretching of weakened muscles and development of deformities. Care should be taken to prevent dropping and inversion of the foot or toes, outward rotation of the lower limbs, flexion of the knees and hips, and adduction of the shoulders when the deltoid is paralysed. Facial, abdominal, gluteal muscles, opponens of the thumb are frequently neglected and allowed to stretch with resultant permanent crippling. The most useful splint is one of the double Thomas pattern, with foot pieces and malleable arm pieces, capable of alteration to suit the recovering muscle function.

In cases with involvement of respiratory muscles raising the foot of the bed 2–3 feet and injection of atropine may save a patient from drowning in his own secretions. Feeding should be carried out by the bowel.

In all paralysed cases prolonged immersion in hypertonic saline baths hastens the disappearance of the hyperæsthesia. A brisk aperient, liberal supply of fluid, firm bed, and immediate splinting are the chief points in the treatment of the acute stage. In this second or convalescent stage the treatment may be summarised as follows:—

1. Obtain the early coöperation of the parents for long-continued rest in order to achieve the best result of which the patient is capable.
2. When the tenderness has gone commence muscle re-education. The results achieved by a masseuse, who has had special training in muscle re-education, will be three times as good as those obtained by a well-meaning amateur.
3. Radiant heat and saline baths are useful.
4. Splinting must be constantly supervised and modified in order to prevent stretching of the weaker muscles by the pull of stronger opposing groups.
5. Deformities develop quickly. Scoliosis, hyperextension of the great toe, adduction of the shoulder, and genu valgum are easily corrected at their first appearance and all are preventable.
6. If abdominal muscles are paresed a well-fitting cloth corset should be fitted, even during recumbency, to prevent stretching of the weakened muscles.
7. Standing may be allowed for a few minutes daily after some months, but not if a position of deformity is assumed in order to stand.
8. Sitting and crawling, which favour flexion of hips, and scoliosis and foot-drop should be avoided.
9. The number of cases in which complete recovery is to be obtained in infantile paralysis is greatly extended by keeping the patients from walking during the first year and in many during the second year also.
10. When it is decided that no more improvement is occurring or that the time has come to allow walking, a brace should be worn by any patient when an unnatural position of the limb is assumed in standing or walking.
11. If the patient is of school age, arrange at the outset for regular lessons.

BRITISH PROVIDENT ASSOCIATION

MANSION HOUSE MEETING

On June 8th the Lord Mayor of London presided over a meeting to make known the aims of the British Provident Association for hospital and additional services.[1] The Prince of Wales, in opening the meeting, said that when the British Provident Association launched its fully developed scheme a few weeks ago he sent them the following message:—

"As President of King Edward's Hospital Fund for London, I have had the opportunity of following closely the development of the proposals of the British Provident Association. They are designed to meet the needs of those who now find it difficult to get treatment of serious illness at a price within their means. I believe the cooperative method of the Association to be the right one, and I shall watch the progress of the Association with great sympathy and interest."

Because he firmly believed in the Association, it gave him great pleasure to repeat that message in person and convey to Lord Lloyd, who had agreed to help in launching the scheme, and to his other friends on the Council, his sincere wishes for the success of the venture. Work, which was badly needed, was being done to help people of moderate means to meet the grave difficulties and expense of serious illness. The schemes to this end had not been hastily or suddenly conceived. He had watched them developing and maturing since 1927, when the committee set up by himself as President of King Edward's Hospital Fund investigated the whole matter. That committee believed that there were great possibilities of development in these schemes; he shared that belief, for it was one of our strongest characteristics as a nation that we liked to stand upon our own feet, and not be beholden to others. That was the essence of the British Provident Association schemes. To the question, "How is provision to be made for us?" the answer was, "Provide for yourselves"—an answer that most appealed to British people. In order that these schemes might be successful—and he was confident they could be successful—what was needed was that all concerned should coöperate to solve their own problem. In every organisation, and in every area throughout the country, there were people who felt the difficulty and the needs; if those people would get together, talk the scheme over among themselves, and tell the British Provident Association what their needs were, they would best help one another to find a way out of their present difficulties. In conclusion his Royal Highness said:—

"What I particularly want to impress upon you is this: cooperation and self-help are the motive forces upon which this Association relies—they are the forces which alone can solve the many grave problems that confront the world to-day. And, if they are employed to the full, I am confident they will solve this problem too."

Lord **Lloyd** said that for the working-class patient there were the voluntary and public hospitals; for those who could afford to pay substantial charges there were nursing homes; while in between was that great body of people who had only moderate means. For these the sudden calamity of a dangerous illness or a serious operation would be more than likely to prove a disaster from which their finances could not recover. Two proposals were now being put forward to meet this state of things.

The first was for the provision of sorely needed hospital and nursing home beds at reasonable charges. To provide such a bed would cost on an average £1000, and it would suffice for the sickness needs in one year of rather more than 100 families. Therefore, if each head of a family put up one payment of £10, he had provided his share of the capital cost of the accommodation needed for himself and his wife for life, and for his children till they reached the age of 21. Capital cost was the actual cost of putting up the building and equipping it for the reception of patients. The cost of maintenance would, of course, still have to be provided by the patient, but in these beds the cost of maintenance would be brought down to a figure within the reach of moderate means, and this would be one of the most important advantages to the contributor. The second proposal was for the provision of some means whereby the cost of maintenance during serious illness and of heavy surgical fees could be substantially, if not wholly covered. The Association had for ten years past worked out and tested very carefully schemes on these lines, and the yearly subscription payable had been fixed at the lowest rate that prudence and experience prescribe. These schemes were, in fact, the development which the King's Fund recommended—they were designed to enable people of moderate means to provide the capital cost of the accommodation which they so badly need, and then by yearly subscriptions of an amount suited to their circumstances to lighten the financial burden of serious illness. A thousand beds were immediately required to mitigate the urgency of the problem, and for that 100,000 £10 contributors were needed. These beds would be provided either in or contiguous to existing voluntary hospitals, or else in new and separate buildings.

---

[1] The Lancet, May 7th, p. 993.

The scheme had been launched only a few weeks ago, but already very numerous inquiries had been received, while subscribers were being registered on the books in increasing numbers.

Sir ALAN ANDERSON expressed his satisfaction at the financial help and encouragement which had been received from King Edward's Hospital Fund, the City Companies, and from many influential people. He expressed his belief in the success which would attend the scheme, pointing out as an example the remarkable growth of the Hospital Savings Association.

Lord MOYNIHAN, who said he was present on behalf of the surgical profession of the country to give support to the scheme which Lord Lloyd had outlined, referred to the wonderful march of science during the past 50 years, and the great progress that had been made in every department of life. In that march medicine had kept pace, and contrasting past and present he referred to the terrible anxiety of Sir Astley Cooper when he had to remove a small growth from the head of George IV. The hospitals in the Crimea stank a quarter of a mile away, and Lister, who in Lord Moynihan's opinion was the greatest benefactor man had ever had, had spoken of the hospitals of his early career as pest houses. Since then surgery had progressed infinitely, and while Lister had made surgery safe for the patient, it now remained to make the patient safe for surgery. Preparation and treatment might be needed for days, weeks, or months, and for this institutional care was required. The voluntary hospital system was one of the greatest glories of the present day, and in those hospitals the poor obtained the best possible treatment. The people for which the British Provident Association scheme was intended could not avail themselves of these institutions, while the strain on their purses would be too great for them to obtain the same adequate treatment that the poor obtained through charity.

Lord DAWSON OF PENN said that side by side with the decreased capacity of the public to pay there had grown up an increased cost of living and of medical treatment. This was due to the growth of knowledge, which had put at the service of medicine increased methods of investigation of great advantage to the individual and to the community. Diagnosis could be made more accurately, and the treatment not only restored the patient to more complete health but it might often get a bread-winner back to work promptly. These things, however, might be beyond the financial resources of an individual, for the increased efficiency of treatment meant its increased cost. The public was now taking a greater interest in health matters, and endeavours to investigate diseases in their earlier stages were seen to be needed. He believed that no scheme of insurance should confine itself to serious illness; rather it should include within its ambit measures to prevent serious illness. As showing how the cost of treatment had rapidly increased, he said that the expenses of the X ray department in one institution during the last ten years had been multiplied threefold. There was only one way of meeting the needs of the majority, and that was by mass production. There must be insurance, and was not insurance part of the fabric of our daily life? The scheme of the British Provident Association was a pioneer movement, undertaken with full understanding of the difficulties to be faced; it should receive all possible encouragement.

A large and representative group of public men were present, and the meeting terminated informally.

HOSPITAL CONFERENCE AT LIVERPOOL

THE annual joint conference of the British Hospitals Association and the Incorporated Association of Hospital Officers was held at Liverpool from June 9th to 12th.

The subjects for discussion included the need for an active international hospital association, opened (in absentia) by Dr. E. Corwin, of New York; the place of the almoner's department in hospital treatment, opened by Dr. W. H. Maxwell Telling; hospital planning, opened by Col. D. J. Mackintosh; and the ways of maintaining the voluntary hospitals under modern conditions, opened by Major Raphael Jackson.

One of the most topical discussions was that on

Hospital Service for Persons of Moderate Means

This took place on board the *Laurentic* on June 9th and was opened by Major R. H. Thornton, hon. treasurer of the Liverpool Maternity Hospital, from the lay point of view, and by Dr. J. C. Matthews, hon. physician, Liverpool Royal Infirmary, *from the* medical point of view.

THE LAY ASPECT

For purposes of discussion Major THORNTON defined the middle class as the economic class with an income range from £250 to £550 *per annum.* The highest available standard of hospital service, he said, could be commanded only by the very rich or the very poor. Although the voluntary hospitals were no longer purely charitable institutions, they retained a bias in favour of this aspect of their work. The capital and running costs of small private institutions were high and their charges could hardly be less than £7 a week; to the man of moderate means this was a large sum. Moreover, by reason of the immense amount of work which physicians and surgeons performed for nothing, their remunerative working time was curtailed and their fees were consequently nearly double what they would otherwise be. Most voluntary hospitals nowadays provided hospital maintenance and facilities for treatment at low cost, but where this provision was inadequate it should not be impossible for leading insurance companies to finance the erection of middle-class nursing homes, the cost of which would be balanced and a reasonable profit ensured by the premiums payable. Apart from insurance companies, the recent development of municipal hospital services indicated that provision of cheap clinical accommodation might come within their scope. Probably the middle class really needed some form of coöperative scheme analogous to the contributory schemes common among manual workers. The manual worker in the voluntary hospital admittedly got something for nothing. The middle class could hardly expect this, and must be prepared as a group to defray the cost of maintenance and treatment. A number of schemes were in stence but most of them only partially met the ficulty, because there was no clinical accommoda- n provided actually in conjunction with any eme, at rates in conformity with it, and because dical and surgical fees were not usually included. such a scheme was to be secure, an adequate ount of bed accommodation must be available to contributing group, at known charges, if not at rges fixed by the promoters of the scheme. The dical profession must be a party to the scheme in sense of agreeing to a maximum scale of fees. less such a scale was fixed no insurance or ntributory scheme would, in Major Thornton's view, actuarially workable. During recent years the ume of hospital treatment given had increased adily; the medical and surgical work of the country s becoming hospitalised, and the process had taken ce at the expense of the family doctor. It was uable that a middle-class hospital service would y give this process a fresh impetus; on the other nd, cheaper facilities for hospital treatment doubtedly tended to stimulate the hygienic educa- n of the community; this in turn produced a ner intolerance of even minor disease, and an rease in general medical practice. Nor was there thing in a middle class hospital service to dis- rage coöperation between the family doctor and hospital staff. Specialisation of diagnosis and atment was the trend of evolution in medical ence, and the requirements of the specialist would better met in a well-equipped hospital of 100 beds n in 100 stuffy bedrooms in 100 semi-detached las. An income limit would have to accompany agreement limiting professional fees. As a tative outline of a middle class hospital service a large urban area he suggested that a joint mmittee representing the municipal health depart- nt and the local voluntary hospitals and their dical staffs should select a general hospital, of ich one section would be chosen for conversion o the required number of private wards. A leading urance company or the local hospitals' contributory eme, if one existed, would be asked to undertake actuarial and administrative work. Applications enrolment would contain a sworn copy of the plicant's last statement of income to the inland enue. A medical board, in conjunction with the motors of the scheme, would draw up a tariff fees for consultants' attendances, surgical opera- ns, special treatment, and nursing; there would o be a standard tariff for maintenance in hospital, sed on ascertained costs. On these, and on the nomic statistics of the area, the rates of contribu- n would be arrived at. Any physician or surgeon ght offer himself for enrolment as a member of medical staff of the service. It would be open to practitioner to recommend his contributor tients to any member of the staff of the service om he might select.

THE MEDICAL ASPECT

Dr. J. C. MATTHEWS thought that the demand middle-class hospital provision had been aggerated, although he was prepared to admit that existed. The disadvantages of such a service luded the red tape, the lack of the personal touch, d the loss of contact with the family practitioner ich institutional treatment involved. Mr. Frank ans, speaking recently at a Round Table luncheon d said: "If, the moment a patient is seriously with pneumonia or appendicitis, he is shipped to a hospital and out of the doctor's hands, where is the interest in the practice of medicine? . . . On the other hand, if a doctor can take a patient into a nursing home and look after him himself, the specialist doing his part of it, you have there the best of consultative work; you have the doctor's knowledge of the patient and the consultant's knowledge of his special branch." Among the schemes shown him on paper, Dr. Matthews said it had been too readily assumed that a surgical operation was the only contingency to be contemplated. Medical cases formed a substantial minority and could not be ignored, while a certain number of cases required more or less elaborate clinical investigation. Though the income limit to be imposed, and the charges to be made for medical attendance must come under discussion in drawing up schemes, there were other matters on which the medical profession would wish to be heard. It was important that the patient should have the widest possible choice of consultant, a choice in which he would be well advised to consult his family doctor. The rules of a hospital providing middle-class accommodation should not only permit the continued attendance of the family doctor, but should limit as little as possible the employment as consultant of any practitioner able to satisfy one or more of the following conditions: (1) that he was holding or had held hospital or other appointments affording special opportunities for acquiring special skill and experience of the kind required for the performance of the service to be rendered, and had had actual recent experience in performing such service; or (2) that he had made special academic or post-graduate study of a subject comprising the service to be rendered, and had had actual recent practice, as already said; or (3) that he was generally recognised by other practitioners in the area as having special proficiency and experience in a subject comprising the service to be rendered.

In large cities, such as London, Liverpool, Birmingham, or Manchester, the demand for middle-class beds might be sufficient to justify the establishment of separate institutions. In the smaller cities and county boroughs the demand would only be sufficient to warrant the provision of beds in association with a local voluntary or municipal hospital, the special equipment and resident staff of which would be used for the patients in such beds. The income limit difficulty could be met partly by providing graded accommodation, the medical fees in the lower grades being on an agreed scale, and those in the higher grades being a matter of private arrangement between doctor and patient. At St. Chad's Hospital, Birmingham, patients paid either 6 guineas a week plus fees for medical attendance, or a composition fee not exceeding 12 guineas to cover everything; this hospital appeared to be conspicuously successful. At Newcastle a block of the Royal Infirmary had recently been opened as a hospital for paying patients under several grades. As long as a hospital was not making a profit more than sufficient to pay a moderate dividend on capital expenditure, and to provide for justifiable improvements and additions, it was not unreasonable to ask doctors to adjust their fees to the means of the patients. He thought that at present most doctors were in favour of keeping the charge for maintenance and the charge for professional attendance entirely separate, but he appreciated the fact that promoters of contributory schemes wanted to know in advance what the cost of appropriate services would be in order to calculate premiums. The British Provident Association published scales of fees payable for surgical operations; these were in the nature of grants-in-aid to the patient who would have to meet surgeons' fees, but it could be assumed that they had been drawn up with professional assistance and were commensurate with actual charges. It must be evident that the provision of hospital accommodation and the promotion of insurance schemes should be kept separate from one another. No hospital should undertake actuarial risk. There should be no reservation of accommodation for the exclusive use of subscribers to a scheme, nor should subscribers be restricted in their choice of accommodation. A grant-in-aid scheme, such as that of the British Provident Association, possessed the elasticity by which the needs of the subscriber could be met.

MEDICINE AND THE LAW

University of Durham College of Medicine : An Inquiry into Administration

Prof. Rutherford Morison's letter, published in our columns on June 4th (p. 1229), has not failed to attract much attention. Clearly there is plenty of support in Newcastle for the view that on the one hand there should be no delay in the impending inquiry into the administration of the College of Medicine and the circumstances of Prof. Hutchens's dismissal; and that, on the other hand, out of respect for the possible recommendations of the tribunal, the College should hesitate to commit itself meanwhile by making an immediate appointment to a professorship of bacteriology. A letter by Prof. H. V. A. Briscoe, professor of inorganic chemistry at the Armstrong College, printed in the Newcastle *Evening Chronicle* of June 8th, shows that, apart from the unfortunate dispute in Prof. Hutchens's case, there is at Newcastle an atmosphere unfavourable to the successful working of academic institutions. It would obviously be improper to prejudice the inquiry by any one-sided version of the present controversy. It seems possible, however, to state the two sides of the case as disclosed in the legal proceedings initiated and lately abandoned by Prof. Hutchens against the College council and Sir Robert Bolam. For this purpose the statement of claim and the defence in those proceedings are summarised here, though it is needless to remind our readers that the legal aspect is not the only aspect that matters, and that these formal legal pleadings are not intended to convey the maximum of information but merely to define the technical issues which a court of law is asked to decide. These legal documents necessarily take no account of many matters of general interest and importance—such, for instance, as the security of tenure in academic appointments or the proper policy of a medical school.

Prof. Hutchens issued his writ on Oct. 15th, 1931, against the University of Durham College of Medicine at Newcastle and against Sir Robert Bolam on behalf of himself and all other members of the College council. His statement of claim set forth the following facts and contentions. He says he was appointed Heath professor of comparative pathology in 1908, and (under University Statute 59) he was a professor of the University so long as he held that chair. It was a whole-time chair; the professor's duties were (*a*) to deliver the lectures and carry out the instructions on pages 48, 49, and 55 of the College calendar, and (*b*) to conduct the work of the bacteriological diagnosis department, with liberty to undertake private special investigations subject to the council's approval. The stipend was £600 (£160 from the endowment and £440 added by the College). He had previously for three years been working at the College, and had on Jan. 1st, 1907, been appointed lecturer in comparative pathology and bacteriology for 12 months; but he contends that he never held this lectureship after his appointment to the Heath chair. In October, 1921, the College council, adopting a report of the finance committee, resolved (inter alia) that his salary be £1400 a year in lieu of his then salary and fees for private work. Prof. Hutchens claims that he performed these duties and received this salary as Heath professor and that his professorship (whether of the University or in the College or both) was not determinable by the College council. On March 13th, 1931, the council passed a resolution that he be given six months' notice terminating his engagement as lecturer in comparative pathology and bacteriology in the College of Medicine, such notice to terminate Sept. 30th, 1931. He received this notice signed by Sir Robert Bolam. He contends that he was not, and for 23 years had not been, lecturer as thus described, and that the notice was invalid to determine his office as professor of comparative pathology. He complains that the College and its council wrongfully treated the notice as valid, withheld his salary, and excluded him from his duties, and he contends that this was equivalent to dismissal; he claims that such dismissal is invalid and wrongful, no effective notice having been given, and he himself having been guilty of no misconduct or breach of duty. He also complains of having been wrongfully excluded from membership of the council, from the academic board of the College, and from the court of governors. Finally he asks the court to grant the following remedies: (1) a declaration that the resolution of March, 1931, was invalid and ineffective to end his appointment as Heath professor; (2) a declaration that he is entitled to membership of the College council, academic board, and court of governors; (3) an injunction to restrain the College, Sir Robert Bolam, and other members of the council from attempting to exclude him from the meetings and proceedings of these bodies; (4) damages; (5) further or other relief; and (6) costs.

In their formal defence the defendants admit certain matters in the statement of claim and deny others. They rely on certain statutes made under the University of Durham Act of 1908, particularly clauses 24, 25, 30, 54, 57, and 59. Under these they claim that the senate of the University can define the terms and conditions, duties and remuneration of offices, and can remove any professor (except the professor of divinity and Greek) from privileges and membership of the University; the council of the Durham Colleges has power to exercise full control over the teaching in the Durham division, and the medical college at Newcastle has similar power and can regulate its constitution and government under its articles of association. The defendants refer to clause 50 of the articles, empowering them to appoint and fix the remuneration of professors and lecturers and to remove these members of the staff if removal is sanctioned by at least one-half of the entire council specially summoned. They say that the College, by letter of December, 1906, appointed the plaintiff lecturer in the department of comparative pathology and bacteriology for a year from Jan. 1st, 1907, and that this appointment was (or must be deemed to have been) renewed thereafter. They contend that the resolution of March, 1908, in effect combined in the person of the plaintiff the offices of Heath professor of the University and of lecturer or head of the department of comparative pathology and bacteriology in the College; the plaintiff, while Heath professor, was liable to the College to perform the duties of this lectureship from year to year as directed by the College. They argue hat the plaintiff's duties were substantially altered n 1921 and 1922 and were further defined in 1928 and 1930 as the minutes of the council's meetings will how. They deny that they have terminated his appointment as Heath professor; they say he is entitled to £167 13*s.* per annum from the endowment. They claim that the notice given to Prof. Hutchens n March, 1931, was valid to determine his office as lecturer or head of the department of comparative pathology and bacteriology in the College. They admit hat he has been dismissed from his office and engagement with the College, but they deny that such dismissal was wrongful; they say the notice was reasonable and proper. They contend that the plaintiff was entitled to be a member of the academic board *qua* lecturer and head of the said department, but not *qua* University professor. His membership of various College bodies ceased when his appointments with the College were terminated. They contend that the defendant council and Sir Robert Bolam have at all times acted bona fide and in the proper exercise of their powers. Lastly, while denying liability, the defendants bring into court the sum of £1232 7*s.* (i.e., 12 months' salary at £1400 less the annual income from the Heath endowment) and say that such sum is in any event amply sufficient to cover any claim he plaintiff may have.

As soon as this defence had been delivered, Prof. Hutchens had choice of three courses of action. In the first place he could go forward with his action, but it was naturally felt that, while litigation was impending and his legal claim was sub judice, the much desired inquiry into the affairs of the College could not proceed. Secondly, he could take advantage of the final paragraph in the defence and could pocket the sum of £1232 7*s.* paid into court by the defendants; the legal effect would be that his action would be discontinued and could never be reopened but the defendants would have to pay his costs. Thirdly, he could discontinue his action without taking the money out of court; in this event, though he would be at liberty to recommence legal proceedings at any future date, he would expose himself to the risk of having an order for costs made against him, he would throw away the chance of making the defendants pay his costs up to date, and he would place himself at the mercy of the governors as regards any payment to be made to him and generally as regards the way in which his case could be dealt with as the result of the inquiry. Prof. Hutchens chose the third course, voluntarily depriving himself of the right to take the money out of court or to obtain his costs. His formal notice of discontinuance was accompanied by a letter from his solicitors making it clear that the claim was withdrawn because Prof. Hutchens's object had been achieved, inasmuch as the governors of the College had decided to hold an inquiry into the whole administration of the College.

These legal proceedings being now out of the way, there seems nothing to obstruct the opening of an impartial inquiry which, in the interests of the medical school at Newcastle, its students and staff, should be as prompt and thorough as possible.

Hospital Patient's Allegations of Negligence Fail

On June 9th and 10th the Lord Chief Justice and a special jury heard the action of Russell *v.* Groves and Lancaster. In May, 1930, the plaintiff was brought to the Bristol General Hospital after a bicycle accident; his right leg was found to be fractured. He now alleged that Dr. L. Lancaster (senior resident officer) on the instructions of Mr. Hey Groves (senior honorary surgeon) had the leg encased in plaster, and that, as a result of no "window" being left in the plaster, the fact was unknown that the leg became septic from a wound in the heel; the poison spread and the leg was amputated first at the knee and later at the middle of the thigh. Mr. Maurice G. Fitzgerald, honorary surgeon to the Teddington and Hampton Wick Cottage Hospital, who attended the plaintiff on his return home from Bristol, described the plaintiff's complaint of pain in his heel and the discovery (after a "window" had been cut in the plaster) of the septic condition of a wound at the back of the heel; in spite of drainage treatment, the first amputation was found necessary. Mr. James E. H. Roberts, of Harley-street, described the second amputation. In cross-examination he agreed that eminent surgeons did not leave a "window" in the plaster encasing a fractured limb; he would not regard it as negligence not to leave an aperture in the plaster. Although these answers might seem to have destroyed the plaintiff's charge of negligence, the Lord Chief Justice did not stop the case but left it to the defendants to call their evidence on the other side. Mr. Hey Groves said it was the common practice among surgeons to case the whole of the limb. Sir Robert Jones, Mr. C. M. Page (surgeon to St. Thomas's Hospital), and Mr. Russell Howard (consulting surgeon to the London Hospital and the Poplar Hospital) agreed with Mr. Hey Groves's evidence. The witnesses said it was safer and better to cover up a wound with plaster than to leave a "window"; there was a bigger danger of infection if a "window" were left, because the exposed part of the limb might bulge, become moist and discharge. The Lord Chief Justice pointed out to the plaintiff's counsel the difficulty of establishing the charge of negligence in the face of the evidence of these expert witnesses. The action was nevertheless continued on the second day when Dr. Lancaster was called into the witness-box. During his examination counsel for the plaintiff intimated that, after hearing both the defendants and surgeons of great eminence, he had advised his client that it was clear that there was no negligence on the part of either defendant. The plaintiff thereupon submitted to judgment, and the jury, on the instructions of the judge, found a verdict for the defendants. The Lord Chief Justice, observing that it was idle to expect that any verdict could be found against either defendant, gave judgment against the plaintiff with costs.

Once again we have a case where the plaintiff's advisers are convinced by the defendant's evidence and withdraw their allegations after putting the defendants to the expense and annoyance of legal proceedings. It seems a pity there is no simpler method of satisfying a plaintiff that his charges are groundless.

MILLER GENERAL HOSPITAL: ANNUAL REPORT.—The annual report expresses great satisfaction that it has been possible to carry on the hospital's work without having to close any of the beds. This however was only made possible by the exceptional legacies received during 1931. The expenditure was £41,557 as compared with £39,614, an increase largely accounted for by renewals and repairs to buildings and plant. The income was £42,769, of which no less than £8722 came from legacies; without them there would have been a deficit of £6510. The number of patients admitted into the wards was 2335; the average stay of each patient was 21 days. There is an urgent need for a new out-patient department, the present accommodation being quite inadequate.

CORRESPONDENCE

THE INCREASE IN CANCER OF THE LUNG

To the Editor of THE LANCET

SIR,—The leading article in your issue of June 4th refers to the increasing incidence of cancer of the lung as a fact. A similar view was put forward by speakers at a recent discussion at the Royal Society of Medicine. With due respect both to yourself and to the speakers in question, I would suggest that this proposition is, as yet, not proven; and that, even if it were, certain qualifications would be necessary in its enunciation for its full significance to be appreciated.

In the first place there is the influence on statistics of increase of medical knowledge and of improved methods of diagnosis. This point needs no labouring. One is more likely to discover a condition if one is familiar with its existence; and also if one has at hand the various diagnostic instruments to supplement data derived from the senses and to differentiate one condition from others which may simulate it. In the third edition of "The Principles and Practice of Medicine" (Fagge and Pye-Smith, London 1891, vol. ii., p. 117, et seq.) we read that "the physical signs caused by mediastinal new growths are due chiefly to their size. . . As may be imagined such large growths . . . cause great dullness on percussion. . . The other physical signs of mediastinal tumours are very uncertain." No one, I imagine, would presume to suggest that we are better clinicians than our predecessors of 40 years ago; and we have therefore no reason to think that we should be in any better position than they were had we to rely on physical examination and such instrumental aids as were then available. Such progress is cumulative; and those who, as students, have had their attention directed to the condition by seeing cases in hospital are more likely to suspect its presence in cases encountered later. We must remember, too, that even now it is not unknown for patients diagnosed—and rightly so—as suffering from empyema, bronchiectasis, or tuberculosis (with tubercle bacilli in the sputum) to be found at operation, or on post-mortem examination, to have a pulmonary new growth. Is anyone prepared to say what proportion of those who in former times appeared in hospital statistics and death returns under these three headings—or even as acute or chronic bronchitis, or pneumonia—would now appear under a different heading?

It is sometimes contended that, even if the clinician of former years were found lacking the pathologists were then at least as good as those of to-day, and would have unmasked their contemporaries' failings. But demonstrators though they be of the soberest of sobering truth, how could they be expected to demonstrate what did not come to their post-mortem rooms? If patients are considered to be suffering from a disease which is not suitable for treatment in the wards of a hospital they do not gain admission, or if admitted do not stay indefinitely. The criteria of suitability have many variable factors, including the state of medical knowledge. Hospital statistics, in fact, are based only to an approximate extent on the principle of the "fair sample" which statisticians require to be present before they will admit the validity of any deductions. Death returns also, although they show the number of deaths known to occur in any given year, must vary as to classification of causes with the increase of our knowledge. Does anyone suggest that no patient died from lymphadenoma before the time of Hodgkin, or from tuberculous caries of the spine before Pott described that condition? I ask that question because I recently heard a speaker at a meeting of a medical society contend that nephritis had been on the increase ever since the first issue of the Registrar-General returns in 1837. He did not mention the fact that Richard Bright did not publish his famous "Reports of Medical Cases" until 1827.

Two other points remain to be mentioned. The first is that the National Health Insurance scheme has given large sections of the community more facilities for medical aid than was previously available to them. Hence earlier detection and hospitalisation of cases—and further vitiation of comparisons based on statistics of the present and former times.

The second point is that Dr. J. C. Dunlop, formerly Registrar-General for Scotland, after examining the statistics of causes of death in Great Britain for the period 1911–1928, came to the conclusion that approximately three-quarters of the observed increase in the death-rate from cancer (all forms) could be accounted for by the ageing of the population, leading to larger numbers *living in those ages in which* the cancer death-rate is high. He also gave as his opinion that the remainder of the increase, subject to an exception in the case of mammary cancer, could with reason be attributed to the better recognition of cancer. (Trans. Med. Chir. Soc. Edin., 1929–30, xliv.)

I am, Sir, yours faithfully,

J. A. STRUTHERS.

Wimpole-street, London, W., June 10th, 1932.

APPENDICITIS

To the Editor of THE LANCET

SIR,—In the discussion on the treatment of acute appendicitis which Sir James Berry's address has aroused I suggest that actual experience as recorded day by day in a surgeon's life is of more value than impressions and recollections, for these are particularly fallacious when the disease is one, as in this instance, which varies so enormously in its severity and in the course which it runs and which above all is distinguished by its treachery.

I have for some years kept my own notes on all my cases of acute appendicitis whether in hospital or in private practice; these notes have all been made by me at the time the patient was under treatment, and present therefore a more uniform and reliable source of information than those obtained by searching through hospital records months or years after the patient has been dealt with. In the belief that these are accurate and have certainly not been compiled with any idea of discrediting the expectant treatment of acute appendicitis (of this my own colleagues in Manchester will, I am sure, acquit me) I submit them to Sir James Berry and those who share his views.

In a consecutive series of 334 cases of acute appendicitis which have been under my care in the past few years, and from which no cases are excluded except a few who were clearly settling down when first seen and one patient (not operated upon) who was dying of appendicular general peritonitis 56 hours after the onset: of these 334 cases, 260 were treated by immediate operation and 11 of these died (case-mortality = 4 per cent.). In the other 74 cases expectant treatment was attempted, always in hospital or nursing home, and of these six died (case-mortality = 8 per cent.). The 260 treated by immediate operation include 87 early and unperforated appendices many of which however were gangrenous, and in this subgroup there was one death and that due to pulmonary embolism ten days after operation. The 74 patients with whom expectant treatment was attempted were mainly cases of (apparently) localised peritonitis which I believed likely to settle down or at the worst to form a well-localised abscess; a few of them were submitted to this treatment because, by reason of age, obesity, or bronchitic troubles, they were regarded as poor subjects for an abdominal operation in the presence of an active infection. But in no case was the gravity of the disease itself regarded as an indication for expectant treatment; the group of 260 immediate operations is loaded with the whole of this class. Of the 74 patients treated on expectant lines, 39 settled down without operation of any kind and, after allowance has been made for the interval appendicectomy which nearly all underwent subsequently, it can confidently be reckoned that these suffered less disturbance and a shorter period of incapacity and caused less work to the nursing staff than they would had they been operated upon in the acute stage. On the other hand 35 did not settle down; in many of these operation was resorted to within two or three days on account of exacerbation of the disease and deterioration in the condition of the patient; in the others and at a rather later stage operation for evacuation of an abscess was performed. The six deaths, of course, occurred in these 35 patients. It may be said that greater faith and persistence in expectant treatment might have reduced the number of these deaths, but I am very sure that some of the patients who survived only did so as a result of timely interruption of expectant treatment by the decision to operate; several times it was plain to me that, though the patient recovered, the delay in operating had narrowed his margin of safety and lengthened his period of illness.

It is impossible here to discuss the many points raised by such figures, but from a consideration of them and of my much larger previous experience I feel strongly that Sir James Berry advocates the expectant treatment of acute appendicitis on much too generous a scale; that there is an important place for this type of treatment I firmly believe and advocate, but it is a very limited place and one which should be marked off by definite boundaries. Sir James Berry in his too optimistic view of the prospects of expectant treatment naturally fails to make adequate recognition of the importance and value of the early operation. I do not think any surgeon who has had extensive personal experience in this branch of surgery during the whole of the past 25 years can doubt that the very early operation for acute appendicitis represents one of the greatest advances in abdominal surgery during this important period of its evolution. It is in consequence of the increasing recognition of this that it is now usual for a surgeon to be called in within a few hours of the first symptom. If the annual statistics for the past ten years of any large hospital are examined I believe it will invariably be found that the case-mortality of acute appendicitis has substantially fallen and that this reduction is due to the increasing proportion of early cases. Certainly the statistics of the Manchester Royal Infirmary (where some 800 cases are dealt with annually) show this.

In conclusion, in so strongly advocating the early operation I do not wish to appear to suggest that this should be performed in every case without regard to the condition of the patient (his age, health, and build) or to the personal resources and equipment of the surgeon.

I am, Sir, yours faithfully,

Manchester, June 7th, 1932. H. H. RAYNER.

THE PREVALENCE OF APPENDICITIS

To the Editor of THE LANCET

SIR,—In continuation of my letter last week may I add that the number of cases of appendicitis under treatment at the London Hospital for the year 1930 was 472. For this information I am indebted to Mr. Stanford Howard.

I am, Sir, yours faithfully,

Harley-street, W., June 13th, 1932. W. H. BATTLE.

TRANSURETHRAL PROSTATECTOMY

To the Editor of THE LANCET

SIR,—In Dr. Hugh Cabot's article (THE LANCET, June 11th, p. 1243) the following is the opening paragraph:

> "Without going too far back into the more or less accidental performance of prostatectomy, one may date the intentional operation for removal of obstruction from those put forward almost simultaneously by McGill in this country and Belfield in the United States. These were in the later 'eighties of the last century. They were not prostatectomies as we now think of them, and though performed by the suprapubic route, were only partial operations and for this reason only partially successful."

It appears to be impossible to make the profession realise that though McGill's work began with nibbling operations upon the prostate, with removal of projecting lobes, and with other partial excisions, it culminated in the removal of the whole prostate, by precisely the same method as we employ to-day. I am sure my old friend Dr. Hugh Cabot does not desire to do injustice to a great surgeon. He would be at once convinced as to the truth of the claim made for McGill by examination of the specimens removed at all his operations; they are still in the Leeds Museum. We possess also the old wooden table upon which McGill placed his patients in the Trendelenburg position which, as many forget, was introduced not for gynæcological but for vesical operations.

I am, Sir, yours faithfully,

MOYNIHAN.

Portland-place, London, W., June 11th, 1932.

To the Editor of THE LANCET

SIR,—Your leading article suggests that transurethral prostatectomy is not employed by surgeons in this country. This is not the case. The indications for this treatment were given in a paper published by me in the *British Medical Journal* in 1926 (vol. i., p. 94). I have found no reason to alter my views. Though I have tried all the newer instruments, I still employ my old technique. All the cases have done well and there has been no tendency for a stricture to form. But it is most important to select suitable cases. I am certain it is useless where the lateral lobes are involved and also in malignant disease. Of the cases with prostatic symptoms which I see in consultation I advise operation in about 60 per cent. And of cases operated upon, transurethral diathermy is employed in about 20 per cent. That is the result of 14 years' experience of this work. If the method is employed for unsuitable cases, it will fall into disrepute. For, when there is a general adenomatous enlargement of the prostate, the obstruction is throughout the urethra. It is difficult to remove it; and, as the pathological condition is a progressive one, it is liable to recur.

I am, Sir, yours faithfully,

Cardiff, June 12th, 1932. T. E. HAMMOND.

DR. ALFRED COX TESTIMONIAL FUND

To the Editor of THE LANCET

SIR,—We feel sure that many of your readers would like to be reminded that the end of the current month closes the term of contribution to the above fund, which is being raised as a token of recognition of the devoted services of Dr. Alfred Cox to the interests of the medical profession.

The response has been good; the excellent portrait, by Sir Arthur Cope, is in the Royal Academy, and the committee are now especially concerned that a larger number of names may be inscribed in the presentation book, which we know Dr. Cox will particularly value.

We would urge those who have not already subscribed to send in their names and addresses, together with a small contribution (in no case to exceed 10*s*., and the amount does not appear in the list) to the hon. treasurer of the British Medical Association, Tavistock-square, W.C.1.

We are, Sir, yours faithfully,
HUMPHRY ROLLESTON,
Chairman, General Committee.
EWEN J. MACLEAN,
June 6th, 1932. Chairman, Executive Committee.

*** Dr. Cox's claim on the respect and regard of the medical profession is such that no words from us could make it stronger. Intending subscribers to the Testimonial Fund, which should imply all medical men who have not yet subscribed, will surely heed the request here made.—ED. L.]

TRAINING IN TUBERCULOSIS

To the Editor of THE LANCET

SIR,—It is to be hoped that Dr. Davidson's timely letter and the discussion it has aroused will result in some practical solution of a grave problem. So far back as 1912, in the report of the Departmental Committee on Tuberculosis, special reference was made to medical education. The Committee were of opinion that additional facilities should be afforded to medical students and practitioners to acquire familiarity with the methods of diagnosis of tuberculosis, more especially in its earlier manifestations, and with its treatment. And they made these recommendations, among others:

1. Medical students and practitioners should be afforded facilities to attend at tuberculosis dispensaries and sanatoria.
2. It is advisable that the tuberculosis dispensaries should, where possible, be directly associated with schools of medicine.

Despite these recommendations, medical training in tuberculosis is still deplorably bad and, with few exceptions, there is little or no coöperation between hospital and dispensary. Unless steps are taken to remedy this lack of organisation, the present mortality figures (over 700 deaths per week in England and Wales alone) of a preventable disease are likely to remain at a standstill.

There is another point on which I would lay emphasis. At the tuberculosis dispensaries there is an abundance of clinical material illustrative of all diseases of the respiratory tract, including many of the most important non-tuberculous conditions. My own experience of work at a chest clinic is that the latter form 50 per cent. of the new cases sent up for opinion, though they are frequently labelled as tuberculous. Students would therefore have the best opportunity at such clinics of learning the differential diagnosis of pulmonary disease with special reference to pulmonary tuberculosis.

The machinery for coöperative organisation exists, and only needs to be put in motion. It may be that the hospital authorities would demand some alterations as regards the details of dispensary work, and indeed I believe that some reorganisation of the dispensary system as such is necessary, and that I have already advocated (*Brit. Jour. Tub.*, July, 1931).

I am, Sir, yours faithfully,
Harley-street, W., June 6th, 1932. PHILIP ELLMAN.

THE OBSTETRIC FORCEPS AND ITS USE

To the Editor of THE LANCET

SIR,—I have read the very interesting paper written by my late colleague Mrs. Dobbin Crawford and I should like to comment upon the sentence:—

> "The application of forceps is only a success—as stated by Berkeley—when their use leaves the mother no worse off than she was before their application, and when the child is born alive."

In my opinion these words under-estimate the high standards which Mr. Comyns Berkeley, Mrs. Crawford, and all other expert obstetricians demand of themselves and, therefore, are not the best teaching to give to students. From the baby's point of view the success of a forceps operation is measured not merely by his life but by his health; he must be born alive *and undamaged.*

Neonatal medicine has made great strides in recent years and the status of the new-born infant is advancing rapidly; it is possible to record great improvements in both diagnosis and treatment of the various injuries which may be suffered by the baby during delivery. But prophylaxis must always be the main object in view, and it is essential that students should be taught the ideal towards which they must strive. No student could do better than learn, as so many have in the past, by attending Mrs. Crawford in her practical work; but those who can learn from her only by reading this paper might fail to grasp the full meaning contained in the one sentence to which I call attention. I am, Sir, yours faithfully,

Liverpool, June 13th, 1932. NORMAN B. CAPON.

THE PREVENTIVE SIDE

To the Editor of THE LANCET

SIR,—The medical profession are frequently criticised for paying insufficient attention to the preventive side of medicine. Sir Arthur Newsholme, Sir George Newman, and now Mr. Somerville Hastings are prominent in stressing this failure. Let us examine this criticism a little more closely.

What diseases are, in fact, preventable wholly or in part? Excluding diseases preventable by public sanitation, port quarantine, good housing, and sufficient food, there remain a moderate number of preventable diseases which can be grouped as follows:

Group I.—Small-pox, diphtheria, and possibly tuberculosis, which can be prevented by immunisation.

Group II.—Industrial diseases.

Group III.—Venereal disease, which can largely be prevented by individual prophylaxis.

Group IV.—Hereditary mental disease and deficiency, which can in part be prevented by sterilisation and segregation.

Group V.—Diseases which are essentially within the province of general practice, such as arise from focal sepsis, overfeeding, overdrinking, oversmoking, obesity; from improper food, clothing, and footwear; from obstetrical injuries.

Now practitioners are constantly urging their patients to have their infected teeth or tonsils dealt with. How often do patients take their advice before the actual onset of rheumatism? Very seldom in my experience. To point out the disfigurement from bad teeth is ten times as effective. How often do patients diet themselves rigorously to prevent the onset of obesity? Very seldom. Yet, when fashion so decrees it, everyone diets at once. It is the same story with foot deformities, the result of narrow pointed shoes. The individual is equally indifferent to possible future ill-health to himself or his children resulting from small-pox, diphtheria, industrial diseases and accidents, and mental diseases. An exception is venereal disease, for the prevention of which individual prophylaxis has had a very definite success.

The lesson is that the individual will only bestir himself for an immediate danger to health, but more distant dangers are ignored and probably always will be. Is the medical profession to be blamed for this fundamental trait in human beings? The State can compel the individual to take the necessary precautions as is done in industrial diseases and, half-heartedly, in small-pox. But the record of our State medical officials is none too brilliant. They did nothing for the prophylaxis of venereal disease, being content themselves to treat end-results, and in the prevention of the increasing menace of mental deficiency and insanity their record is bad. They obstructed the dissemination of contraceptive knowledge to the poor.

I am, Sir, yours faithfully,

Bridlington, June 13th, 1932. P. D. H. CHAPMAN.

THE KING'S COLLEGE HOSPITAL SCHEME

To the Editor of THE LANCET

SIR,—The attention of the medical board of King's College Hospital has been directed to the article published in your issue of May 28th (p. 1172) and to subsequent correspondence upon this subject. While not admitting the accuracy of all the statements made, I beg to inform you that the arrangements are under discussion by the committees concerned. The steps which are being taken will, I confidently hope, remove the objections raised. I need not assure you that the medical staff at King's College Hospital would strongly discountenance any procedure not in accordance with the traditions of medical practice.

I am, Sir, yours faithfully,

W. GILLIATT, M.D., F.R.C.S.,
Chairman of the Medical Board, King's College Hospital.

June 14th, 1932.

FREE TREATMENT AT VENEREAL CLINICS

To the Editor of THE LANCET

SIR,—While endorsing the remarks of Dr. Wansey Bayly and Dr. Browdy, I am inclined to add the trite comment that in lean periods, which we have had before, it is possible to become over-pessimistic. A greatly esteemed surgeon and teacher, interested in social phenomena, used to point out to his classes the close relationship existing between the rise and fall in the incidence of venereal disease and similar movements in the graph of business activity. In its economic effects business depression attacks all fluctuating incomes, including those of medical and surgical specialists without exception, dentists, barristers, architects, and others. It is undoubtedly true that there are V.D. patients attending public clinics who in ordinary circumstances would demand something better; but when a pukka chartered accountant sells you your ticket for the greyhounds is it, after all, so very surprising?

A reform considerably overdue is the removal of the crude V.D. advertisements from public lavatories, an illustration of bureaucratic medicine at its worst. Unless meant to direct strangers in London or elsewhere the posters serve no useful purpose, for they offend many well-disposed persons and by promoting ribald remarks are very largely self-destructive, cost the public something, and constitute a standing offence to many decent-minded people. Large numbers of children visit public conveniences, and I know of nothing more embarrassing than trying to evade the searching questions of small boys and girls curious to know. "What are secret diseases?" and "What sort of a place is St. Swithin's Hospital?"

I am, Sir, yours faithfully,

H. D. L. SPENCE.

Great Russell-street, W.C., June 13th, 1932.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 4TH, 1932

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 49 (last week 68); scarlet fever, 1502; diphtheria, 709; enteric fever, 23; acute pneumonia (primary or influenzal), 675; puerperal fever, 54; puerperal pyrexia, 96; cerebro-spinal fever, 51; acute poliomyelitis, 4; encephalitis lethargica, 14; dysentery, 13; ophthalmia neonatorum, 102. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on June 7th–8th was as follows: Small-pox, 81 under treatment (last week 84 under treatment and 2 under observation); scarlet fever, 1526; diphtheria, 1317; enteric fever, 10; measles, 2211; whooping-cough, 396; puerperal fever, 15 (plus 5 babies); encephalitis lethargica, 227; poliomyelitis, 3; "other diseases," 99. At St. Margaret's Hospital there were 15 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 73 (29) from measles, 7 (3) from scarlet fever, 32 (10) from whooping-cough, 21 (5) from diphtheria, 59 (11) from diarrhœa and enteritis under two years, and 33 (5) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London occurred at Manchester and Ipswich. Liverpool reported 18 deaths from measles and 6 from diphtheria. Four fatal cases of whooping-cough occurred at Liverpool, 3 each at Birmingham and Walsall.

The number of stillbirths notified during the week was 294 (corresponding to a rate of 39 per 1000 total births), including 40 in London.

FATAL CASE OF SMALL-POX.—The case in which small-pox was mentioned as the cause of death in the return for the week ended May 28th was that of a man, aged 56, admitted to Queen Mary's Hospital, Sidcup, on April 19th, from Lambeth Hospital, where he had been since March 9th suffering from myeloid epulis, which was being treated with radium. On arrival at Queen Mary's Hospital, Dr. C. Ellingworth informs us, he had considerable radium reaction about the face and swallowed food with difficulty. He had some pyelitis and had been treated with hexamine. On May 3rd he complained of headache, and he was found to have a temperature of 103° F., with some slight abdominal pain and crepitations at the base of both lungs. The urine was free from albumin. On the morning of May 7th he developed a papular rash on the forehead and hands which was rather mixed up with the radium irritation. Dr. H. M. Pereira, who was called in consultation, confirmed the diagnosis of small-pox, and the patient was removed to Longreach Hospital, where he died. Dr. D. M. Connan tells us that the cause of death was certified thus: 1. (*a*) Myeloid epulis. (*b*) Pyelitis. 2. Small-pox discrete; vaccinated in infancy.

THE SERVICES

REVISION OF THE ARMY MEDICAL SERVICES

REORGANISATION in the Medical Services of the Army has been announced which should result in consolidating and extending the teaching, research work, and the professional opportunities of officers of the R.A.M.C. and in enhancing the status of the Royal Army Medical College. After the Great War a great advance was made in coordinating the professional activities of the Corps by the creation of Directorates of Hygiene and Pathology, with Advisory Committees of eminent civilian doctors, and by the appointment of a Consulting Physician and a Consulting Surgeon to the Army from among the serving officers of the Corps.

The War Office statement continues :—

> Owing to the large size of the Army at that time, these directorates and appointments were located at the War Office as part of the staff of the Director-General, Army Medical Services. Now that the size of the Army has been reduced and more largely concentrated in the principal military stations, the organisation of the medical directorate has permitted of some decentralisation and the opportunity has been taken to concentrate at the Royal Army Medical College *the heads of all the specialist* branches of medicine and surgery. The revision of departments involved has been secured by transferring the Director of Pathology, the Consulting Physician to the Army, and the Consulting Surgeon to the Army, from the War Office to the Royal Army Medical College and absorbing the appointments of Professors of Pathology, Tropical Medicine, and Military Surgery respectively. Each of these officers will as at present have an assistant professor under him, and in the case of medicine and surgery these officers will form the visiting medical and surgical staff of the Queen Alexandra Military *Hospital, Millbank. The Director of Pathology will still* control the pathological work in commands as well as carry on his professorial work. The teaching staff of the College will now become the consultants and advisers of the Director-General, Army Medical Services, at the War Office, and will be available for consultation in Commands when required. The composition and location of the Directorate of Hygiene has not been changed. The consultant and professor in each case, though normally of colonel's rank, may be promoted to major-general should he come up for promotion in the ordinary course while holding the appointment. The appointment of Commandant and Director of Studies at the College will, in future, carry with it the rank of major-general, but on the other hand the Deputy-Director, Army Medical Services, at the War Office will, when the next appointment is made, be a colonel instead of a major-general. Thus, of the possible 11 major-general's appointments open to Royal Army Medical Corps Officers, five are now of a professional nature and six administrative.

This is a definite step forward in the professional work of the Corps, whose advance has been evident since the war. It should do much to remove the erroneous impression that adequate professional work is unobtainable in the Army. In consequence also of the elaboration of motor transport in recent years many of the smaller hospitals in commands have been closed and the patients concentrated in central hospitals fully equipped with all the special departments made necessary by modern methods of diagnosis and treatment. This has resulted in specialisation in all branches of medical, surgical, and pathological work being now the rule rather than the exception.

A civilian inspector of the teaching and civilian examiners will be appointed by the Director-General A.M.S., after consultation with the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England, thus promoting uniformity in the educational courses of R.A.M.C. officer and the civilian doctor.

NEW APPOINTMENTS.

As a result of the revision Colonel John Weir West, C.M.G., and Colonel Ralph Bignell Ainsworth, D.S.O., both late R.A.M.C., are promoted Major-Generals as from June 15th.

Major-General West, Hon.-Surgeon to H.M. the King, and late A.D.M.S. for the Burma District, and Consulting Surgeon to the Army, resumes the latter status in becoming Professor of Military Surgery at the R.A.M. College.

Major-General Ainsworth, Hon. Physician to H.M. the King, *continues to occupy* his post as Commandant and Director of Studies at the College, the post having now become one to be held by a Major-General.

The *London Gazette* also announces :—

Colonel A. C. H. Gray, O.B.E., M.B., K.H.S., late R.A.M.C., from Director of Pathology, War Office, to be Director and Professor of Pathology, Royal Army Medical College.

Lieutenant-Colonel and Brevet Colonel (temporary Colonel) W. P. MacArthur, D.S.O., O.B.E., M.D., F.R.C.P.I., K.H.P., from Consulting Physician to the Army, to be Professor of Tropical Medicine, Royal Army Medical College, and Consulting Physician to the Army.

Major and Brevet Lieutenant-Colonel J. M. Weddell, F.R.C.S., Royal Army Medical Corps, from Professor of Military Surgery, to be Assistant Professor of Military Surgery, Royal Army Medical College.

Major J. Heatley-Spencer, O.B.E., M.D., Royal Army Medical Corps, from Professor of Tropical Medicine, to be Assistant Professor of Tropical Medicine, Royal Army Medical College.

Lieutenant-Colonel H. M. J. Perry, O.B.E., Royal Army Medical Corps, from Professor of Pathology, to be Assistant Professor of Pathology, Royal Army Medical College.

ROYAL NAVAL MEDICAL SERVICE

THE following appointments have been notified: Surg. Comdrs. *F. C.* Wright to *Colombo*, and *E. St. G. S.* Goodwin to *Pembroke*, for Chatham Barracks. Surg. Lt.-Comdr. A. G. L. Brown to *Curacoa.*

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. R. Erskine-Gray to *Pembroke*, for Chatham Hospital.

Surg. Lt. E. R. G. Passe to *Victory*, for Haslar Hospital.

ROYAL ARMY MEDICAL CORPS

The undermentioned Lts. to be Capts.: R. R. Leaning and W. G. Harvey.

Lt. C. J. Dobbin relinquishes his temp. commn.

TERRITORIAL ARMY

Capt. L. F. E. Jeffcoat to be Maj.

INDIAN MEDICAL SERVICE

Lt. (on prob.) G. R. M. Apsey to be Capt. (prov.) (on prob.).

AUXILIARY AIR FORCE

Flying Officer H. W. Walter is promoted to the rank of Flight Lieutenant.

ORDER OF THE NILE

The King has given to Major Robert George Archibald, C.M.G., D.S.O., licence to wear the Insignia of the Second Class of the Order of the Nile, conferred upon him by the King of Egypt, in recognition of valuable service rendered while in the employment of the Sudan Government.

INTERNATIONAL CONGRESS FOR LIGHT.—The second International Congress for Light (biology, biophysics, and therapeutics) will be held at Copenhagen *from* August 14th to 18th, under the presidency of *Dr. Axle* Reyn. The principal subjects of discussion will be: the action of the general light baths in tuberculosis; climatological research in its relation to public health; instruction in actinology; the rôle of pigment in light biology; and the therapeutic effect of general light baths. A report will be presented by the international committee for the determination of a standard unit of measurement for ultra-violet radiation, and a morning will be devoted to demonstrations at the Finsen Institute. Speakers from England will include *Sir Henry Gauvain, Sir Leonard* Hill, and Dr. W. Kerr Russell. During and after the conference there will be opportunities of seeing the neighbourhood, and on August 19th and 20th it will be possible to visit Odense, the Julemærke Sanatorium and Vejlefjord Sanatorium, returning via Hamburg. Excursions to Sweden and Norway can be arranged.

OBITUARY

WILLIAM WILLIAMS KEEN, M.D.

EMERITUS PROFESSOR OF SURGERY, JEFFERSON COLLEGE, PHILADELPHIA

WE regret to announce the death on Tuesday, June 7th, of Prof. William Williams Keen, the American surgeon of international fame, in his 96th year. In him the medical profession loses a leader of surgical thought and accomplishment whose practical teaching of his subject ranged from 1866 to 1907, just over 40 years.

PROF. W. W. KEEN

William Williams Keen was born in Philadelphia in 1837, only 60 years after the American Declaration of Independence. He was indeed a link with history. In 1853 he completed his preliminary education at the Philadelphia High School and entered the Brown University with the original intention of becoming a clergyman, but the study of chemistry and physics decided him to enter for medicine. In 1861 the American Civil War broke out and although not yet qualified he served with the troops in a medical capacity while he contrived to continue his professional studies. These he completed in 1862 and re-entered the Army with his qualifications. On leaving the Army he came into close contact with Weir Mitchell, already a physiologist whose work was known in Europe, and he collaborated with him and Morehouse, his junior, in the publication of some interesting papers on neurological surgery, then quite a new subject. Two years of post-graduate work in Paris, Vienna, Berlin, and London followed, and in 1866 Keen returned as head of the Philadelphia School of Anatomy and began to teach anatomy and operative surgery and surgical pathology. He competed unsuccessfully for the chair of anatomy at the Jefferson College, but many years later was appointed to that of surgery, having in the interval held other teaching appointments and secured a very large surgical practice. At Jefferson College, until his retirement in 1907, he taught increasingly large classes of students and established a surgical clinic of the first importance, so much so that when, in 1907, having reached his seventieth year, he made an extended tour round the world, he found his former pupils in almost every country that he visited.

Prof. Keen was a prolific author alike on surgical and on religious and social subjects, and always his views were fearless and clear-cut and revealed him as a great controversialist, simple in expression, reasonable, and direct. He wrote an early history of practical anatomy, a history of the first Baptist Church of Philadelphia, and a work on the Surgical Complications of Typhoid Fever—these in sequence. He collaborated with Dr. William White in an admirable treatise on surgery generally, he edited Heath's Practical Anatomy, he published numerous collections of essays and addresses on such themes as animal experimentation, the treatment of war wounds, early professional developments in the United States, and artistic anatomy, and he contributed to and edited Keen's System of Surgery.

Necessarily such a veteran was the recipient of many honours, and Keen held honorary degrees as M.D., LL.D., Ph.D., or Sc.D., from (among others) the Universities of Harvard, Yale, Toronto, St. Andrews, and Upsala; he was an hon. F.R.C.S. of England, Edinburgh, and Ireland, and had been president of the American Surgical Association and of the College of Physicians in Philadelphia, while he presided over the International Congress of Surgery in Paris in 1920. His long and valuable life was essentially a happy one. He was devoted to his profession in every aspect, he rejoiced in his deeply held religious convictions, and he had a remarkable gift of making friends.

Lord Moynihan allows us to publish the following notes of his personal relation with William Williams Keen :—

" Dr. Keen's death, at the age of 95, will be deeply mourned by the multitude of his friends in all parts of the world. A man's age is not to be counted by the years he has lived, but, in many cases at least, by the freshness of his enthusiasms. Dr. Keen's eagerness in every form of intellectual pursuit never ceased to astonish his friends, sometimes even perhaps to embarrass them, for in pursuit of knowledge he spared no man ! In England Dr. Keen found many men who regarded him with warmest affection, and with admiration for his pioneer and long continued service to the cause of surgery. His reputation became international half a century ago ; 32 years ago he was made an Honorary Fellow of the Royal College of Surgeons of England, and in praise of Lister then made a speech which none who heard it will ever forget.

" As an author he was prolific. He wrote, with Dr. William White, a Text-book of Surgery, which was the first in our language to be based upon bacteriology ; it almost alienated our affections from 'Erichsen.' Many men considered him—though having heard Nicholas Senn and J. B. Murphy, I could never agree—the greatest teacher of clinical surgery America had ever known. His virility and force were well matched with sincerity and invulnerable accuracy, and tempered with sobriety ; authentic qualities expressing his own character and habits of thought. He was the protagonist of those ideas to which most members of our profession adhere in relation to vaccination, vivisection, laboratory research. The public in America regarded him as the incorruptible champion of medicine. With him controversy was never coarsening. He was a man of decided views emphatically expressed ; but he was, no less, the very flower of culture, the very perfume of courtesy. He bore himself on all occasions with a genial simplicity, and showed a fine sense of respect for opposing views which disarmed criticism and often encouraged agreement.

" He had the happiest knack, excelled not even by Osler, of keeping in touch with his friends in all lands. I have a number of his letters, many written after he was 90 in most beautiful script, and with the steadiest of hands. Since he first stayed with me 25 years ago almost every letter of his bore a reference to some incident that had then occurred, to some member of my family, or to some plan maturing for our next meeting. It was justly said of Osler that many men in many lands hugged the belief that they were his particular cronies. That was certainly true in regard to Keen.

"Keen was one of the very first surgeons in the world to realise the truth and high importance of Lister's teaching. His great predecessors, Gross and Agnew, had laboured under the tyrannies of almost inevitable, raging infections. Keen helped to inaugurate the new era. His work on the brain, nervous system, abdominal organs, upon the ravages of typhoid fever in their surgical relations, indeed upon all branches of surgery—and he practised all with immense success—was perhaps the most considerable and the most inspiring of that of any surgeon in the States. The simplicity and flawless integrity of his life, his exquisite sense of humour, his power of provoking it, and his capacity for swift and often unanswerable reply, all helped to create a personality that no man who knew him will ever be able to forget. He once told me that the secret of life was to mix merry laughter with earnest labour. He, most assuredly, proved that to be true. If wisdom is a right conception of the ends of life, my very dear old friend Dr. Keen was indeed among the wisest of men."

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Patents and Designs Bill

In the House of Commons on Tuesday, June 7th, Mr. Hore-Belisha (Parliamentary Secretary to the Board of Trade) moved the second reading of the Patents and Designs Bill which, he said, was to give effect to the recommendations of the Departmental Committee.

Sir F. E. Fremantle said he wished to raise the question of the patenting of food and drugs, and to call attention to a point of great and growing importance which was omitted from the Bill designedly because of the difficulty of the subject. He would like to ask for some explanation of the attitude of the Ministry in regard to this most important point. He did not think it was sufficiently known that the patenting of a large number of the most important medical drugs and medicines recently discovered was subject to a patent law which had unfortunately put our research at the mercy of certain foreign countries.

VITAMINS

The position was quite extraordinary. He thought most people would know the vital difference to the foods of the country between fresh butter and margarine. Margarine was coming more and more into use naturally enough, and yet it had been discovered of recent years that what it really lacked was a certain substance called vitamin D. The discovery of vitamin D was made only a few years ago, and it was due to research in this country when it was discovered how by the use of ultra-violet rays it could be produced out of a certain material called ergosterol. Unfortunately the patent for the manufacture of this vital material was taken out by a worker in an American university, and it was known as the Steenbock patent. It gave patent rights over not only America, but all other countries, including this country, for all forms of manufacture of vitamin D. Prof. Steenbock gave the patent rights over to the universities, and the universities submitted it to a committee and it was run by the committee for the benefit of that university. The patent rights were made out with definite conditions in this country which were found to be very hampering to research. It was considered that the patent ought not to cover the more modern processes which had not been discovered there but here, and would, as was the custom in this country, be given to the research workers for their free use. The university had built up very large sums and was a wealthy corporation, and no one cared to challenge their rights. They were extracting large royalties from all who used this process of treatment of our food, and they were also hampering our research work. A large amount of the very best work was done in these subjects by the big manufacturing houses, but they found it more worth while to pay the royalty rather than fight a corporation of that sort. They paid the royalties themselves and passed it on to the consumer, so that our consumers suffered because our patent rights were not sufficient to protect us against the patent rights taken out in America.

BIOLOGICAL PRODUCTS

In the same kind of way we were at the mercy of a foreign patent with regard, for instance, to the subject of insulin. When insulin was discovered in Canada the patent right was given over to a Canadian university, which most nobly gave it to our Government and our Government passed it on to the Medical Research Council, and they were able to use the patent rights in insulin and to prevent any commercialisation of it which would have been fatal to a large number of our people, and they had seen that it was properly used and produced. There was a third product, the discovery by Dr. and Mrs. Dick working together in Chicago. They discovered the toxin and the antitoxin for scarlet fever. They took out patent rights and gave them to the University of Chicago. They were used commercially and mercilessly by the committee running the trust, and the result had been to hinder and to stop very largely research in this country.

OPEN DOOR FOR RESEARCH

These matters were put before the Board of Trade by the Medical Research Council three years ago, with a view to giving evidence before the Departmental Committee upon whose report this Bill was founded, yet no action had been taken officially to incorporate their representations in this measure. He maintained that that was a most serious blot, although there might be good reasons for their omission. Perhaps it might be one of expediency. It was a very difficult subject, and he felt that the matter required considerable explanation. If the Board of Trade were able to give good reasons for not including this most important principle in this measure he hoped that they would be able to give some kind of undertaking that they were seriously considering this matter, which went right to the root of the health of the people of the country. It was a matter which required investigation, even if it could not be brought in as an amendment to the Bill. A conference was held by the British Medical Association which was also attended by the President of the College of Physicians and Surgeons and members of the Medical Research Council, during which the matter was gone into, and they came to the conclusion that they would first of all see the Board of Trade and having seen them they were asked to consider whether it was not advisable to move an amendment to the measure. They had been asked not to move any amendment at the present time. They could only implement that undertaking if they were given some pledge from the Board of Trade that they recognised the seriousness of the position. The matter required a good deal of international work, and required a good deal of thought as to what they could do in this country. The medical profession definitely maintained that the results of research should be open to everybody and above board, and should be applied to universal use, and that there should be no patent rights whatever as regards what were called animal medicines and products, vitamins, sera, antitoxins, and the rest of them. No patents should be allowed whatever which were a disadvantage to other countries. As regarded synthetic compounds made by chemical drug houses and so on, it would be impossible that patents should be given for those purposes, but as a common practice and a right one in this and other countries medical men should not be allowed to take out patents to make a profit by them. It would be compulsory, as the conference suggested, that patents for such articles for medical use should be dedicated to universities or some public trust or body for general use. They required legislation to deal with all these matters. No doubt the League of Nations and their work and international matters come in, but it took a long time to get anything through the League of Nations, as they knew full well, or internationally. In the meantime they ought to act. There were signs that they were not acting and that the Department did not understand these things, and that the Government were paying no attention whatever to them. He hoped that they would receive some explanation from the Board of Trade that they realised the seriousness of the situation and that they would do something to consider the matter in due course.

THE QUESTION OF EXPROPRIATION

Sir Stafford Cripps said that there was one way in which the difficulty referred to by Sir F. E. Fremantle could be overcome, and that was by giving the Government power to expropriate patents. At present the Government had that power in respect of inventions for warlike purposes. He (Sir S. Cripps) did not see any reason why a useful article, such as some medical or food product, should not also be subject to acquisition by the Government in the same way. There was no reason why an invention should not be capable of being put into safe custody to be used under the disposition of the Medical Research Council or other such body for the benefit of the whole country.

Sir Boyd Merriman (Solicitor-General), after giving an assurance that any representations with regard to amendments to the Bill would be carefully considered by the Government in Committee, said that there was already power to compel people to make anything which was the subject of a patent available for public service. That involved payment of royalties to the inventor, and he thought that there was no more reason why a person who had spent his life in research and invention in connexion with health should be deprived of the fruits of his labours than any other inventor. The Government were not prepared as at present advised to consider any question of expropriation without compensation of any form of invention. (Cheers.)

Sir Stafford Cripps said that he admitted that compensation should be paid on the same terms as in regard to munitions.

Sir Boyd Merriman said that Sir F. E. Fremantle had said that anything which affected health or medical research should be made open to the public and not be subject to a patent at all. This Bill was professedly a modest Bill. It was designed to give effect to the recommendations of the Departmental Committee.

EXPLOITATION REPUGNANT TO THE MEDICAL PROFESSION

Dr. O'Donovan said that there was a great difference in the outlook on life between the legal and the medical profession, and it was because of that that Sir Boyd Merriman had not followed wholeheartedly the lead given him by Sir F. Fremantle. The medical profession had always resented any suggestion coming from the Government that the profession had the right to exploit the people. There was no question that patents could be used for exploitation, and the idea that the sons of Hippocrates should be unfaithful to an oath which had held for over 2000 years had been made for the first time that evening. To him the suggestion was repulsive. It was true that chemists were entitled to the result of their studies in organic chemistry, but that the results of medical research should be followed by action, and that again protected by patent, was a conception which was new to the ideals of medicine. He was grieved to hear it from the front bench, and he hoped that the point which had been put so boldly by Sir F. E. Fremantle would be borne in mind by the Government in the future discussions on the Bill.

The Bill was read a second time.

The Children Bill

In the House of Lords on June 13th the Children and Young Persons Bill was further considered in Committee. The Earl of Onslow (Chairman of Committees) was in the chair. Clause 48 provides that no child under 12 years shall be employed. Lord Banbury carried an amendment to omit the provision that by-laws made by local authorities might authorise the employment of children under 12 by their parents or guardians. Viscount Astor moved a new clause providing that a local authority might make by-laws with respect to the employment of persons under 18 years, but not being children. The clause continued :—

> (2) By-laws so made may distinguish between persons of different ages and sexes, and different localities, trade, occupations, and circumstances, and may contain provisions for prescribing: (i) The number of hours in each day or in each week for which and the times of day at which they may be employed; (ii) the intervals to be allowed to them for meals and rest; (iii) the holidays or half-holidays to be allowed to them; (iv) any other conditions to be observed in relation to their employment.
>
> (3) Nothing in this section shall empower a local authority to make by-laws with respect to: (*a*) employment in or about the delivery, collection, or transport of goods except in the capacity of van boy, errand boy, or messenger; (*b*) employment in or in connexion with factories, workshops, mines, quarries, shops, or offices, not being employed in any capacity as aforesaid; (*c*) employment in the building or engineering trades, not being employment in any such capacity as aforesaid; (*d*) employment in agriculture; (*e*) employment in domestic service except as non-resident daily servant; provided that this section shall not come into operation until a resolution has been passed by both Houses of Parliament.

The clause was agreed to. On Clause 55, which makes provisions in regard to juveniles taking part in or being trained for dangerous performances, Lord Balfour of Burleigh moved an amendment to *delete the proviso that no girl under 18 should take* part in any public performance in which her life or limbs were endangered. He said that in families of acrobats training began at a very early age. The amendment was accepted.

National Health Insurance Bill

In the House of Commons on June 13th the National Health Insurance and Contributory Pensions Bill was considered in committee. On Clause 1 Mr. Logan moved to leave out Subsection 1, which provides that a person who becomes employed while treated by any of the provisions of the section as insured shall not on ceasing to be so employed become entitled for that reason to extension of insurance unless during the contribution half-year in which he ceased to be employed and the preceding half-year he was employed during eight contribution weeks. He said that under this Bill the burden was to be borne by the unemployed members of the approved societies. He did not know what would happen in the near future if they denied these people medical benefits. Sir E. Hilton Young said that there was no question of forfeiture of rights under this Bill. It was recognised that there would be hardship in the abrupt termination of insurance rights, and that some extension of insurance rights should be given, even beyond what was strictly legitimate on the actuarial and financial basis of the insurance scheme. The extension that was actually given was an extension of 21 months of free insurance with full benefit, and then an extended year with reduced benefits. That was a very generous extension to save the insurance of the unemployed. Under the Bill a further extension had been made, and anyone who got back to work could immediately start the whole period of extension over again. There must be a practical test of employment, and the test was to be that the insured person must show eight stamps during a year instead of the present farcical test of one stamp.

The Duty on Beer

When the Finance Bill, as amended, was being considered by the House of Commons on report, Sir W. **Wayland** moved a new clause to restore the duty on beer to the level at which it stood before the Budget of September, 1931.

DRINK A CAUSE OF SECONDARY POVERTY

Dr. **Salter** said that in opposing this new clause he spoke for himself and not for his party. The Labour party by a unanimous vote had agreed that its members should have a perfectly free hand in this discussion. At the present time there was less beer being drunk per head in this country than at any previous time in our history. Was that a national calamity? On the contrary, he said that, particularly at the present juncture, it was a national advantage. On this point the Royal Commission on Licensing, which was not composed of teetotallers, but was a very mixed body with a large majority of non-teetotallers in its composition, after 18 months consideration of the subject had expressed itself in no uncertain terms. They said in their report that "a general reduction in consumption of intoxicants ought to be aimed at," and further, that "excessive drinking still persisted in very large measure and that apart from actual intemperance expenditure on intoxicants still reached a figure which was definitely uneconomic."

He had practised as a medical man for over 30 years in one of the poorest boroughs of London and one of the poorest quarters in the whole country. During that time he had been the recipient of very intimate and very sacred confidences. He had been into many thousands of homes and had been able to watch family life from the inside, and he said without hesitation that not in the far distant past but at the present time there were enormous numbers of families whose babies were going short of milk, where children were going without boots, where the whole family happiness was being wrecked, because the father was an excessive beer consumer. Although he agreed that primary poverty was not due to drink yet a very large proportion of secondary poverty was due to drink. It was a distinct national advantage that money should be spent on household necessities rather than on alcoholic drinks.

THE CHANCELLOR'S APPEAL

Mr. **Chamberlain** (Chancellor of the Exchequer) said that while he had budgetted for an increase of revenue amounting to £8,000,000 from this tax he nevertheless expected that if the tax were remitted he would lose not £8,000,000 but £10,000,000. Could he afford to give away £10,000,000 in the present year? All of them, no doubt, could see reasons for hope and confidence in the future. At the same time he did not think that they could feel so satisfied that the worst was over that they could afford to sacrifice any reserves that they might have behind them. He respected the sincerity of feeling of those members who supported this clause, but he appealed to hon. Members who had been returned to support the National Government and had done so because they felt that a National Government would represent this country overseas with a prestige and authority which could not attach to any purely party Government. There was no question of the Government being defeated on this clause; they were not afraid about that, but would hon. Members, even those who felt strongly on this matter, bear in mind that a really substantial vote against the Government on a matter of such importance as this on an essential part of the Budget could not do otherwise than injure and diminish its authority. He asked hon. Members not to forget these great national and international world interests which were about to be discussed, and the future of which might perhaps be decided in the course of the next few weeks, and not take a step at this moment which might do anything to make less the influence and the power that the Government exercised.

POINT OF VIEW OF REVENUE

Mr. **Churchill** said that he admitted the force of much of that which was said by Dr. Salter on the temperance aspect, but when they considered the progress which had been made, perhaps, he admitted, under the influence of high taxation in the past, in the sobriety of this country, no one could consider that the temperance aspect was an urgent aspect in the discussion at the present time. In 1913 there were 183,000 convictions for drunkenness, and in 1931, the last year for which they had complete figures, they had fallen to 53,000. It was perfectly clear that the temperance aspect ought not to sway their opinions about this tax at the present time and that they were entitled to look at it solely from the point of view of revenue.

WHITE BREAD WORSE THAN BEER?

Mr. **Macquisten** said that Dr. Salter and his friends who thought like him had a sour outlook on life, and they thought that beer was bad for the health. A lot of things were damaging to health. He believed that in addition to his duties as a medical man Dr. Salter was a baker. If that was so, he might tell the hon. Member that if he lived in poor benighted Portugal, or in one or two other European countries and sold the white bread which he sold to the masses of the people in Bermondsey he would be sent to gaol for a long period for selling a substance dangerous to human health. (Laughter.) The devitalised stuff which bakers sold, with all the real good taken out of it, and lacking all the things which went to body-building and teeth making, and so on, was thoroughly bad, and the hon. Member and his friends had done more harm than all the brewers in the district round London. (Laughter.) Hon. Members had no idea of the amount of the illicit production of alcoholic liquor which was going on in this country. A favourite stuff was what was called "surgical spirits," which he was informed contained a little castor oil and a very small proportion of boracic acid and could be bought without any prescription in any chemist's shop. Then there was the spirit used by french polishers which contained only a small quantity of wood spirit and appeared to be consumed with comparative safety by many people. There was also the ordinary mineralised methylated spirit which he was told was only consumed by the most abandoned persons, and was sold in some districts in small quantities at 2*d*. or 3*d*. a time. A Government which taxed alcoholic liquors so heavily was asking for such things. Such taxation was the worst and most injurious class legislation.

THE WISHES OF THE POOR

Dr. **O'Donovan** said that a member of his own profession, like one of the sect of the Manichees, had explained to the House the evil of drink and had advised them to take to that drink which was exclusively designed by nature for the nourishment of calves. (Laughter.) He (Dr. O'Donovan) intervened in the debate only to express to the House and to the Government the wishes of the poor in his constituency. He had received, and perhaps other hon. Members had had the same experience, a petition self-organised by the poor of his constituency and signed by 6000 people asking him to do something to persuade the Chancellor of the Exchequer to lower the tax on beer. He repudiated entirely the suggestion that the poor in the mass were horrid and made up of potential drunkards The poor to-day could not afford a glass of beer. When he was a medical student there was a rhyme "A little of what you fancy does you good." When one was promoted to a higher sphere one understood that a little alcohol was an anodyne for the discomforts of this weary world. When one was even further promoted to live among the highbrows one understood that a little alcohol removed those inhibitions which kept one in a state of chronic melancholia. (Laughter.) In English inns the greatest influences of human kindness had been cogitated by decent men for the good of their fellows. (Cheers.) He would remind the House that the London Hospital, one of the greatest in this country, was founded by a meeting of simple workpeople, business men, and merchants, in a London tavern. (Cheers.) Those who supported this new clause were animated by no spirit of animosity to the Government. They sympathised with the burden that the Chancellor of the Exchequer carried, and if they voted against him they did it for one reason—that that sore feeling of the poor should not lack registration and that this matter might be kept open for consideration at another time.

The clause was negatived.

Taxation of Research Stipends

Sir J. WITHERS moved a new clause to provide that stipends paid to research students at universities should be treated for purposes of taxation as earned income, and not as unearned income as decided recently by the Inland Revenue authorities.

Major ELLIOT said that he was glad to be able to give the assurance that where a student was getting a stipend on the terms that he devoted time research on a special subject he would be assessed under Schedule E and be eligible for earned income allowance.

The new clause was, by leave, withdrawn.

HOUSE OF COMMONS

THURSDAY, JUNE 9TH

Mentally Defective Children

Wing-Commander JAMES asked the President of the Board of Education the number of mentally defective children for whom special educational facilities had been provided in the last pre-war year and during the last three years; and the additional cost involved in the current year.—Sir D. MACLEAN replied: The average number on the registers of special schools for mental defective children were as follows: Year ended March 31st, 1914, 13,563; 1929, 15,479; 1930, 15,308; 1931, 15,269; and 1932 figures not yet available.

In regard to the last part of the question, I regret that information is not available as to the expenditure incurred on these schools as distinct from special schools for defective children of other types.

Married Women and Health Insurance

Miss RATHBONE asked the Minister of Health what would be the estimated saving to the funds of approved societies under the National Health Insurance Acts if all women on marriage were put into Class K, subject to the proviso that any woman who could prove 26 weeks of employment and of contribution subsequent to the date of her marriage and within two years of that date should be entitled to be restored to the full benefits provided by the Act, either as at present provided or, alternatively, as proposed to be applicable to married women under the Bill now under consideration.—Sir E. HILTON YOUNG replied: There are no data available for the formation of any reliable estimate of the financial effect of the change referred to by the hon. Member.

MONDAY, JUNE 13TH

The Purification of Mussels

Mr. REMER asked the Minister of Agriculture if he could make any statement as to the progress made by the experimental station at Conway for the purification of mussels; what steps he was taking, in conjunction with the Minister of Health, to make the advantages to public health more widely known; and to secure an extension of these purification tanks.—Sir JOHN GILMOUR replied: Mussels have been cleaned successfully on a commercial scale at Conway for about 15 years. The Ministry takes every opportunity of bringing the advantages of purification to the notice of those interested in shell-fish beds which have been closed owing to pollution, and acts in close consultation with the Ministry of Health in these matters. My hon. friend will be aware that a Bill introduced by my hon. friend the Member for Ormskirk to enable local authorities to provide or contribute towards the provision of means for cleansing shell-fish has recently been approved by Parliament.

Milk Reorganisation Committee

Brigadier-General CLIFTON BROWN asked the Minister of Agriculture whether he would request the reorganisation committee for milk now sitting to issue before September some announcement indicating the lines on which their proposals would be evolved, so as to help and be a guide to those engaged in fixing milk prices next autumn.—Sir JOHN GILMOUR replied: The fact that the problems confronting the milk industry are being actively investigated by the Milk Reorganisation Commission should in itself conduce towards friendly and helpful negotiation on milk prices next autumn, but while it is within the Commission's discretion to make interim representations to me if they think fit, I do not feel that it is desirable that I should give them instructions in the matter.

Cerebro-spinal Fever

Mr. GROVES asked the First Lord of the Admiralty how many cases of cerebro-spinal meningitis or other form of cerebro-spinal disease had been reported in the Navy since Jan. 1st last; how many of them had been fatal; and how many of them had been subjected to vaccination, revaccination, or inoculation during the six months prior to the attack.—Lord STANLEY replied: Ten cases of cerebro-spinal meningitis have been reported since Jan. 1st last, and four of them have proved fatal. According to available records, three of the total number had been subjected to vaccination, none to revaccination, and one to inoculation within six months of the attack. The information concerning vaccination, &c., is not obtainable in two of the cases. All were cases of epidemic cerebro-spinal meningitis ("spotted fever"), and none of them was of the post-vaccinal type.

TUESDAY, JUNE 14TH.

First-aid Equipment on Motor Vehicles

Mr. GUY asked the Minister of Transport which officials were responsible for examination of first-aid equipment when a public service vehicle was presented for licensing under the Road Traffic Act.—Mr. WOMERSLEY (Lord of the Treasury) replied: No statutory responsibility rests upon any particular official for the examination of first-aid equipment. In fact, however, it is inspected by the Public Service Vehicle Examiners when vehicles are presented for examination prior to licensing.

Imported Liquid Eggs

Mr. ANSTRUTHER-GRAY asked the Minister of Health what steps were taken by his department to ensure that liquid eggs imported into this country were certified fit for human consumption before being sold for that purpose.—Mr. ERNEST BROWN replied: Liquid eggs are subject to examination on importation into this country, and if they are found to be unfit for human consumption they may be seized and destroyed.

ASSOCIATION OF PORT SANITARY AUTHORITIES DINNER.—This Association met in London this year, and on June 9th the Corporation of the City of London entertained to dinner some 100 of its members and friends at the Guildhall. The Burgomaster of Antwerp was among the guests. The Lord Mayor and other speakers emphasised the important work done by members of the Association in protecting the country from the insidious introduction of infection, as well as in caring for the conditions of life of men on ships. The labours of Dr. Collingridge and Dr. Herbert Williams for the Port of London in the past, and the present activities of Dr. W. M. Willoughby and Dr. C. F. White were singled out for special praise. The President for the year, Mr. Cyril Gamon, referred to the loss the Association had recently sustained in the death of Dr. W. R. Dearden, of Manchester, and gave some account of the work of the Association since its formation in 1898. The prevention of the importation of infectious disease had been one of its most important duties. The methods by which this object was achieved included the circulation of information regarding the prevalence of cholera, yellow fever, plague, and small-pox in ports abroad, the devising of the procedure to be adopted when infected ships arrived in English ports, and rat repression. The Association had made representations from time to time to the Government of the day on such matters as food inspection, the medical inspection of aliens, the hygiene of crew spaces, and many of the recommendations made had been put into force. Matters dealt with during the last year had included the prevention of the importation of sterilised meat, the question of ownership of unsound food, the scale of charges for certificates of deratisation and exemption from deratisation granted under the International Sanitary Convention, the transport of live fish for human food, smoke abatement, and the discharge of sewage from ships into docks and enclosed harbours.

extension over again. There must be a practical test of employment, and the test was to be that the insured person must show eight stamps during a year instead of the present farcical test of one stamp.

The Duty on Beer

When the Finance Bill, as amended, was being considered by the House of Commons on report, Sir W. **Wayland** moved a new clause to restore the duty on beer to the level at which it stood before the Budget of September, 1931.

DRINK A CAUSE OF SECONDARY POVERTY

Dr. **Salter** said that in opposing this new clause he spoke for himself and not for his party. The Labour party by a unanimous vote had agreed that its members should have a perfectly free hand in this discussion. At the present time there was less beer being drunk per head in this country than at any previous time in our history. Was that a national calamity? On the contrary, he said that, particularly at the present juncture, it was a national advantage. On this point the Royal Commission on Licensing, which was not composed of teetotallers, but was a very mixed body with a large majority of non-teetotallers in its composition, after 18 months consideration of the subject had expressed itself in no uncertain terms. They said in their report that "a general reduction in consumption of intoxicants ought to be aimed at," and further, that "excessive drinking still persisted in very large measure and that apart from actual intemperance expenditure on intoxicants still reached a figure which was definitely uneconomic."

He had practised as a medical man for over 30 years in one of the poorest boroughs of London and one of the poorest quarters in the whole country. During that time he had been the recipient of very intimate and very sacred confidences. He had been into many thousands of homes and had been able to watch family life from the inside, and he said without hesitation that not in the far distant past but at the present time there were enormous numbers of families whose babies were going short of milk, where children were going without boots, where the whole family happiness was being wrecked, because the father was an excessive beer consumer. Although he agreed that primary poverty was not due to drink yet a very large proportion of secondary poverty was due to drink. It was a distinct national advantage that money should be spent on household necessities rather than on alcoholic drinks.

THE CHANCELLOR'S APPEAL

Mr. **Chamberlain** (Chancellor of the Exchequer) said that while he had budgetted for an increase of revenue amounting to £8,000,000 from this tax he nevertheless expected that if the tax were remitted he would lose not £8,000,000 but £10,000,000. Could he afford to give away £10,000,000 in the present year? All of them, no doubt, could see reasons for hope and confidence in the future. At the same time he did not think that they could feel so satisfied that the worst was over that they could afford to sacrifice any reserves that they might have behind them. He respected the sincerity of feeling of those members who supported this clause, but he appealed to hon. Members who had been returned to support the National Government and had done so because they felt that a National Government would represent this country overseas with a prestige and authority which could not attach to any purely party Government. There was no question of the Government being defeated on this clause; they were not afraid about that, but would hon. Members, even those who felt strongly on this matter, bear in mind that a really substantial vote against the Government on a matter of such importance as this on an essential part of the Budget could not do otherwise than injure and diminish its authority. He asked hon. Members not to forget these great national and international world interests which were about to be discussed, and the future of which might perhaps be decided in the course of the next few weeks, and not take a step at this moment which might do anything to make less the influence and the power that the Government exercised.

POINT OF VIEW OF REVENUE

Mr. **Churchill** said that he admitted the force of much of that which was said by Dr. Salter on the temperance aspect, but when they considered the progress which had been made, perhaps, he admitted, under the influence of high taxation in the past, in the sobriety of this country, no one could consider that the temperance aspect was an urgent aspect in the discussion at the present time. He repudiated entirely the suggestion that the poor in the mass were horrid and made up of potential drunkards The poor to-day could not afford a glass of beer. When he was a medical student there was a rhyme "A little of what you fancy does you good." When one was promoted to a higher sphere one understood that a little alcohol was an anodyne for the discomforts of this weary world. When one was even further promoted to live among the highbrows one understood that a little alcohol removed those inhibitions which kept one in a state of chronic melancholia. (Laughter.) In English inns the greatest influences of human kindness had been cogitated by decent men for the good of their fellows. (Cheers.) He would remind the House that the London Hospital, one of the greatest in this country, was founded by a meeting of simple workpeople, business men, and merchants, in a London tavern. (Cheers.) Those who supported this new clause were animated by no spirit of animosity to the Government. They sympathised with the burden that the Chancellor of the Exchequer carried, and if they voted against him they did it for one reason—that that sore feeling of the poor should not lack registration and that this matter might be kept open for consideration at another time.

The clause was negatived.

Taxation of Research Stipends

Sir J. Withers moved a new clause to provide that stipends paid to research students at universities should be treated for purposes of taxation as earned income, and not as unearned income as decided recently by the Inland Revenue authorities.

Major Elliot said that he was glad to be able to give the assurance that where a student was getting a stipend on the terms that he devoted time research on a special subject he would be assessed under Schedule E and be eligible for earned income allowance.

The new clause was, by leave, withdrawn.

HOUSE OF COMMONS

THURSDAY, JUNE 9TH

Mentally Defective Children

Wing-Commander James asked the President of the Board of Education the number of mentally defective children for whom special educational facilities had been provided in the last pre-war year and during the last three years; and the additional cost involved in the current year.—Sir D. Maclean replied: The average number on the registers of special schools for mental defective children were as follows: Year ended March 31st, 1914, 13,563; 1929, 15,479; 1930, 15,308; 1931, 15,269; and 1932 figures not yet available.

In regard to the last part of the question, I regret that information is not available as to the expenditure incurred on these schools as distinct from special schools for defective children of other types.

Married Women and Health Insurance

Miss Rathbone asked the Minister of Health what would be the estimated saving to the funds of approved societies under the National Health Insurance Acts if all women on marriage were put into Class K, subject to the proviso that any woman who could prove 26 weeks of employment and of contribution subsequent to the date of her marriage and within two years of that date should be entitled to be restored to the full benefits provided by the Act, either as at present provided or, alternatively, as proposed to be applicable to married women under the Bill now under consideration.—Sir E. Hilton Young replied: There are no data available for the formation of any reliable estimate of the financial effect of the change referred to by the hon. Member.

MONDAY, JUNE 13TH

The Purification of Mussels

Mr. Remer asked the Minister of Agriculture if he could make any statement as to the progress made by the experimental station at Conway for the purification of mussels; what steps he was taking, in conjunction with the Minister of Health, to make the advantages to public health more widely known; and to secure an extension of these purification tanks.—Sir John Gilmour replied: Mussels have been cleaned successfully on a commercial scale at Conway for about 15 years. The Ministry takes every opportunity of bringing the advantages of purification to the notice of those interested in shell-fish beds which have been closed owing to pollution, and acts in close consultation with the Ministry of Health in these matters. My hon. friend will be aware that a Bill introduced by my hon. friend the Member for Ormskirk to enable local authorities to provide or contribute towards the provision of means for cleansing shell-fish has recently been approved by Parliament.

Milk Reorganisation Committee

Brigadier-General Clifton Brown asked the Minister of Agriculture whether he would request the reorganisation committee for milk now sitting to issue before September some announcement indicating the lines on which their proposals would be evolved, so as to help and be a guide to those engaged in fixing milk prices next autumn.—Sir John Gilmour replied: The fact that the problems confronting the milk industry are being actively investigated by the Milk Reorganisation Commission should in itself conduce towards friendly and helpful negotiation on milk prices next autumn, but while it is within the Commission's discretion to make interim representations to me if they think fit, I do not feel that it is desirable that I should give them instructions in the matter.

Cerebro-spinal Fever

Mr. Groves asked the First Lord of the Admiralty how many cases of cerebro-spinal meningitis or other form of cerebro-spinal disease had been reported in the Navy since Jan. 1st last; how many of them had been fatal; and how many of them had been subjected to vaccination, revaccination, or inoculation during the six months prior to the attack.—Lord Stanley replied: Ten cases of cerebrospinal meningitis have been reported since Jan. 1st last, and four of them have proved fatal. According to available records, three of the total number had been subjected to vaccination, none to revaccination, and one to inoculation within six months of the attack. The information concerning vaccination, &c., is not obtainable in two of the cases. All were cases of epidemic cerebro-spinal meningitis ("spotted fever"), and none of them was of the post-vaccinal type.

TUESDAY, JUNE 14TH.

First-aid Equipment on Motor Vehicles

Mr. Guy asked the Minister of Transport which officials were responsible for examination of first-aid equipment when a public service vehicle was presented for licensing under the Road Traffic Act.—Mr. Womersley (Lord of the Treasury) replied: No statutory responsibility rests upon any particular official for the examination of first-aid equipment. In fact, however, it is inspected by the Public Service Vehicle Examiners when vehicles are presented for examination prior to licensing.

Imported Liquid Eggs

Mr. Anstruther-Gray asked the Minister of Health what steps were taken by his department to ensure that liquid eggs imported into this country were certified fit for human consumption before being sold for that purpose.—Mr. Ernest Brown replied: Liquid eggs are subject to examination on importation into this country, and if they are found to be unfit for human consumption they may be seized and destroyed.

Association of Port Sanitary Authorities Dinner.—This Association met in London this year, and on June 9th the Corporation of the City of London entertained to dinner some 100 of its members and friends at the Guildhall. The Burgomaster of Antwerp was among the guests. The Lord Mayor and other speakers emphasised the important work done by members of the Association in protecting the country from the insidious introduction of infection, as well as in caring for the conditions of life of men on ships. The labours of Dr. Collingridge and Dr. Herbert Williams for the Port of London in the past, and the present activities of Dr. W. M. Willoughby and Dr. C. F. White were singled out for special praise. The President for the year, Mr. Cyril Gamon, referred to the loss the Association had recently sustained in the death of Dr. W. R. Dearden, of Manchester, and gave some account of the work of the Association since its formation in 1898. The prevention of the importation of infectious disease had been one of its most important duties. The methods by which this object was achieved included the circulation of information regarding the prevalence of cholera, yellow fever, plague, and small-pox in ports abroad, the devising of the procedure to be adopted when infected ships arrived in English ports, and rat repression. The Association had made representations from time to time to the Government of the day on such matters as food inspection, the medical inspection of aliens, the hygiene of crew spaces, and many of the recommendations made had been put into force. Matters dealt with during the last year had included the prevention of the importation of sterilised meat, the question of ownership of unsound food, the scale of charges for certificates of deratisation and exemption from deratisation granted under the International Sanitary Convention, the transport of live fish for human food, smoke abatement, and the discharge of sewage from ships into docks and enclosed harbours.

MEDICAL NEWS

University of Cambridge

On June 10th the degree of B.Chir. was conferred (by proxy) on G. H. A. Graetz.

Royal College of Surgeons of England

A meeting of the Council was held on June 9th, with Lord Moynihan, the president, in the chair. Lord Dawson of Penn, president of the Royal College of Physicians of London, was introduced, and admitted an honorary Fellow of the College.

Diplomas of Fellowship were granted to the following candidates who were successful *at the recent examination*:—

Philip Rowland Allison, M.B. Leeds, Guy's; Frederic Herbert Bentley, M.B. Manch., Guy's; Francis Arthur d'Abreu, B.M. Birm., St. Bart.'s; Robert Saunders de Bruyn, L.R.C.P., Guy's; Charles Leslie Swinnerton Duke, M.B. Sydney, St. Bart.'s; Maxwell Philip Ellis, M.D. Lond., Univ. Coll.; William John Ferguson, M.B. Lond., Guy's; Robert Allen Fitzsimons, M.B. Lond., Charing Cross; Botelego Marcus Fonseka, M.B. Lond., Birm. & Univ. Coll.; Philip Edward Glynn, L.R.C.P., Leeds & St. Bart.'s; Francis John Hector, M.D. Bristol; Franz Konrad Saddler Hirschfeld, L.R.C.P., Oxford & London; Reginald Keene, M.B. Lond., St. Bart.'s; Gopal Shankar Kelkar, M.B. Bombay, London; Hasan Yusuf Khwaja, M.B. Bombay, London & Guy's; Maurice Basil Lavery, M.B. Belf., Birm.; Maurice Lee, M.B. Durh.; Oswald Vaughan Lloyd-Davies, M.B. Lond., Middlesex; David Lurie, B.M. Oxf., London & Guy's; Thomas Keith Selfe Lyle, M.R.C.P., Camb. & King's Coll.; Archibald Hector McIndoe, M.B. N.Z., Otago & St. Bart.'s; Wylie McKissock, M.B. Lond., St. George's; Joseph Mintzman, L.R.C.P., Middx., Lond., & Guy's; John Havelock North, M.B. N.Z., Otago & St. Bart.'s; Gangadhar Martand Phadke, M.B. Lond., Univ. Coll.; Ralph Francis Phillips, M.B. Lond., St. Bart.'s; James George Reid, L.R.C.P., Oxf. & St. George's; Arthur Haden Richardson, M.B. Birm., London; Nicholas Harold Lloyd Ridley, M.B. Camb., St. Thomas's & Lond.; James Sloan Mutrie Robertson M.B. Glas., St. Bart.'s; Enid Helen Rockstro, M.B. Lond., Univ. Coll. & Guy's; Muhammad Abdul Hameed Siddiqi, M.B. Lucknow, St. Bart.'s & Lond.; Charles Gordon Sinclair, M.B. Lond., St. Bart.'s; Melvill Digby Sheppard, M.B. Lond., Univ. Coll.; George John Sophian, M.R.C.P., St. Bart.'s & St. Mary; Denis James Ross Steen, L.R.C.P., Camb. & St. Thomas's; William Harry Tandy, L.R.C.P., Birm. & St. Bart.'s; Vernon Cecil Thompson, L.R.C.P., Cardiff & St. Bart.'s; Gordon Oxburgh Tippett, M.B. Lond., St. Thomas's; James Whillis, M.D. Durh.; Joseph Mendel Yoffey, M.D. Manch., Cardiff.

Diplomas of Membership were granted to Henry Barcroft (Camb. and St. Mary's) and Abdul Rashid (Punjab), and the Licence in Dental Surgery to Albert Brooke Bateman (Adelaide and Liverpool).

The following were elected examiners for the ensuing year:—

Dental Surgery.—Surgical section: Mr. H. S. Clogg, Mr. L. Bathe Rawling, Mr. Russell Howard, Mr. Gwynne Williams, Mr. C. [illegible] Wakeley. [illegible]: Mr. P. N. B. Odgers, Pr[illegible] E. S. Frazer, and Mr. Basil Hu[illegible] Mellanby, Prof. G. A. Buckm[illegible] Prof. Samson Wright.

[illegible].—Elementary Biology: Mr. T. J. Evans, Mr. G. P. Mudge, Mr. C. C. Hentschel, and Mr. A. J. Grove. Anatomy: Prof. R. B. Green, Prof. W. E. Le Gros Clark, Prof. H. A. Harris, Prof. E. B. Verney, and Prof. Hamilton Hartridge. Pathology: Prof. William Bulloch, Mr. C. H. Fagge, Dr. R. G. Canti, and Mr. C. E. Shattock. Midwifery: Mr. A. W. Bourne, Mr. Sidney Forsdike, Mr. L. Carnac Rivett, and Mr. Malcolm Donaldson.

Diploma in Public Health.—Part I.: Prof. J. W. H. Eyre. Part II.: Dr. James Fenton.

Diploma in Tropical Medicine and Hygiene.—Major-General D. S. Harvey and Dr. G. Carmichael Low.

Diploma in Ophthalmic Medicine and Surgery.—Part I.: Mr. W. S. Duke-Elder and Mr. Charles Goulden. Part II.: Mr. Affleck Greeves.

Diploma in Psychological Medicine.—Dr. J. Godwin Greenfield.

Diploma in Laryngology and Otology.—Part I.: Mr. Norman [illegible] Musgrave Woodman. Part II.: Mr. [illegible]

[illegible] *and Obstetrics.*—Mr. J. D. Barris.

[illegible] *Radiology.*—Part I.: Prof. Woodburn Morison. Part II.: Dr. Douglas Webster.

National University of Ireland

University College, Cork.—At recent examinations the following candidates were successful:—

M.D.

In psychological medicine.—P. J. Courtney.

M.CH.

Edmond Bourke.

M.A.O.

Edmond Donovan.

M.B., B.CH., & B.A.O.

T. A. Kelly (with second-class honours), D. J. Barry, S. T. Cuddigan, R. J. S. Doherty, R. A. Good, M. S. O'Callaghan, W. F. O'Connell, J. A. O'Driscoll, and Mary O'Mahony.

D.P.H.

Part II.—T. A. Neville.

University of Oxford

Under the will of Mrs. Jackson, wife of a former rector of Exeter College, property has been left to the college which will partly be used for the foundation of a medical fellowship.

C. R. Green has been elected to the Schorstein Research Fellowship in medical science for two years.

University of Bristol

A dissertation by Percy Phillips has been approved for the degree of M.D. At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B., CH.B.

Part I.—Margaret A. W. Hawkes and A. V. House.

Part II.—A. L. Eyre-Brook (first-class honours), O. E. L. Sampson (second-class honours), K. P. Beaubrum, G. T. Bevir, R. G. C. G. Carlson, A. McD. Davies, H. F. M. Finzel, F. E. Fletcher, J. R. Gibbs, and Frances N. Salisbury.

FINAL EXAMINATION FOR L.D.S.

Helena C. L. Blinkworth and W. V. Whiteford.

London Hospital Medical College

A course of lectures by Dr. J. R. Marrack, on the Structure of Molecules in Relation to Biology and Medicine, is now in progress at the college. They are given at 5.15 P.M. on Tuesdays and Thursdays, and are open to students and members of the medical profession.

On Friday, June 24th, at 3 P.M., Sir William Goschen *will distribute the prizes of the past academic year.*

Fripp Fellowship in Child Psychology

Applications are invited for the Sir Alfred Fripp Fellowship in Child Psychology, which is of the value of £300 per annum, and is tenable for two years. The investigations undertaken by the Fellow will be carried out in the children's department of Guy's Hospital, London. Further particulars may be found in our advertisement columns.

Donations and Bequests

The late Mrs. Beatrice Emily Smythe, among other bequests, left £1000 to the Elizabeth Garrett Anderson Hospital; £250 to the Children's Hospital, Halifax, Nova Scotia; £1000 to the League of Mercy; £500 to the Lady Chichester Hospital, Hove; and £500 to the Chelsea Hospital for Women.

Scottish Hospitals Liaison Committee

The Secretary of State for Scotland has reconstituted the Central Liaison Committee for Voluntary Hospitals in Scotland for the period to March 31st, 1935. The purpose *of the Committee is to "act in liaison between* the Department of Health for Scotland and the regional committees of voluntary hospitals in Scotland, to assist in keeping the Department in touch with voluntary hospital opinion, and, in the development of hospital services in Scotland, to foster coöperation between the voluntary hospitals and the local authorities in each region." The members are Lord Mackenzie (chairman); Sir David Wallace, F.R.C.S.; Mr. C. F. Henderson; Sir Alexander MacEwen; Sir James Macfarlane; Colonel D. J. Mackintosh, M.B.; and Major-General James Thomson, M.B. The secretary is Mr. Niven F. M'Nicoll, of the Department of Health for Scotland.

European Committee for Mental Hygiene

Following on the first International Mental Hygiene Conference, held at Washington in May, 1930, Mr. Clifford Beers, the founder and secretary-general, met some 50 European representatives at the Union Interalliée in Paris on May 29th to initiate preparations for a second congress to be held in Paris in 1935, and to assist in constituting the European Committee for Mental Hygiene. The delegates from England were Mr. L. G. Brock (chairman of the Board of Control), Sir Hubert Bond (senior commissioner). Dr. R. D. Gillespie and Dr. Doris Odlum (joint hon. secretaries of the British Council for Mental Hygiene), and Dr. J. R. Rees (hon. deputy director of the Institute for Mental Psychology, *Tavistock-square*). The business meetings were followed by scientific sessions held at the psychopathic hospital Henri Rousselle at the invitation of Prof. Toulouse. The subjects included discussions (1) on a report by Prof. Rüdin (Berlin) on the place of eugenics in preventive mental hygiene; (2) on the *facilities* available in Europe for the treatment of mental disorder without legal formalities; (3) on international unification of statistics in relation to mental disease. A second European reunion is to be held in Rome in September, 1933, by invitation of the Italian representatives. Sir Hubert Bond was appointed British representative on the European executive and Dr. Gillespie the British corresponding *member of the European council.* Prof. Toulouse was elected president of the 1935 congress with Dr. Genil Perrin as hon. secretary.

Prof. Toulouse was elected president of the 1935 congress with Dr. Genil Perrin as hon. secretary.

University of Birmingham

Mr. William Gemmill, hon. surgeon to the Queen's Hospital, Birmingham, has been appointed joint professor of surgery in place of the late Prof. William Billington.

Harveian Society of London

The Buckston Browne dinner of this society was held at the Connaught Rooms, London, on June 9th, the president of the society, Mr. Cecil P. G. Wakeley, being in the chair. After the loyal toasts, prosperity to the Harveian Society was proposed by Lord Riddell in an amusing speech in which, while he certainly regarded the great Harvey from a new angle, he showed himself quite familiar with the significance of Harvey's discoveries. Speaking as president of the Medico-Legal Society, Lord Riddell said that he desired to show his practical interest in the prosperity of a sister association by instituting a permanent memorial to the signal generosity of Sir George Buckston Browne in connexion with the Harveian Society. He therefore proposed, he said, to present to the Society a loving-cup which should bear an inscription recording the association of the gift with Buckston Browne.

The President, in reply, explained that the annual Buckston Browne dinner, and the Harveian prize and medal, were given by Sir Buckston in memory of his gallant and only son, Lieut.-Colonel George Buckston Browne, who fell in the Great War. He referred to the pleasure which he, and all the members of the Society, had felt in Sir Buckston's knighthood, recalling that they had heard from him, 30 years ago, one of the finest of their series of Harveian lectures entitled "Twenty-five Years of Urinary Surgery in England." Referring to the centenary celebrations of last year, the president reminded the society of their visit to Hempstead Church, Harvey's burial place, when a silver patten was presented to the church by the Society, which also undertook to rehang the bells when the tower was re-erected by the Royal College of Physicians of London. The sum required for that purpose he said was £400, of which £210 had been received, while Dr. Turtle, the treasurer of the Society, would be pleased to receive subscriptions. Mr. Wakeley concluded by suggesting that the loving-cup, which Lord Riddell was presenting, should bear the three names of Harvey, Buckston Browne, and Riddell.

The toast of the Visitors was then proposed by Dr. A. H. Douthwaite, who coupled with it the names of Prof. William Wright, president of the Anatomical Society of Great Britain and Ireland, and Prof. Allen Mawer, provost of University College, London.

Prof. William Wright, in reply, said that it would not be inappropriate to the occasion to add something to the personal history of Harvey. Sir D'Arcy Power's biography, he said, stated that when Harvey's resting-place at Hempstead was first visited by the late Sir Benjamin Ward Richardson in 1847, the lead in which the remains were lapped was already corroded—the result being a rent through which on one occasion a frog jumped out, and from which a thick, dirty fluid oozed. Richardson was anxious to know whether there were still any of the mortal remains of Harvey within, and on a further visit to Hempstead, accompanied by, among others, Sir George Paget, representing Harvey's old college, Caius, he took with him a small mirror, a magnesium light, and other appliances. Paget narrated the sequel to the late Sir William Ridgeway, who was Prof. Wright's informant. It was now found that in the interval, owing to a further collapse of the lead, the rent was almost closed. The party shrank from opening the case and viewing the great discoverer "clothed with all the dishonours of corruption," but yet felt it incumbent upon them to settle whether any of the remains were present or not. At this juncture Richardson took his stick or umbrella firmly in his hand, pushed it through the rent and, moving it up and down, met such obstruction as to convince himself and the other members of the party that no inconsiderable part of the former Warden of Merton was still there. The incident, said Prof. Wright, had, probably for reasons of delicacy, up till now been almost universally suppressed, but he felt no apology was needed for telling the story and relieving the necrolater visiting Hempstead of any dubiety as to the contents of the shrine. This he found to be one more example of the strange tricks which time and fate play with our relics. "Could there be," he asked, "any sharper contrast than that between the fate of Harvey's material remains and his great and glorious spiritual legacy?"

Prof. Mawer also replied.

The guests were numerous and representative, and included the Directors-General of the Navy, Army, and Royal Air Forces, Sir Peter Chalmers Mitchell, Prof. W. R. Halliday, the Presidents of the College of Obstetrics and Gynæcology, the Royal Society of Medicine, the Medical Society of London, the Hunterian Society, the Listerian Society, and the Chelsea Clinical Society.

Dr. Jessie MacGregor Prize, Edinburgh

This prize for the present triennial period has been divided equally between Miss Elsie Porter, M.D. Edin., for her work on the therapeutic uses of drugs of the digitalis group, and Miss Helen May Russell, M.D., F.R.C.P. Edin., for her work on human and experimental relapsing fever. The prize is awarded for original observations by a woman who has qualified in medicine from Edinburgh.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, June 21st.—5.30 P.M., General Meeting of Fellows. Ballot for election to the Fellowship.

Thursday.—2 to 5.30 P.M., Urology. Exhibition of instruments. 5.30 P.M., Sir John Thomson-Walker: Some Changes and Problems in Urology.

Saturday.—Disease in Children. Annual Provincial Meeting at Alton.

MEDICO-LEGAL SOCIETY.

Thursday, June 23rd.—8 P.M. (at 11, Chandos-street, Cavendish-square, W.), Mr. Alexander Paterson: Should the Criminologist be Encouraged? To be followed by a discussion.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.

Wednesday, June 22nd.—5.30 P.M., Sir Thomas Lewis: Recent Observations on the Causation of Raynaud's Disease. (Annual Oration).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, June 20th to Saturday, June 25th.—Prince of Wales's Hospital, Tottenham, N. Post-graduate course in general medicine, surgery, and the specialties. All day. Specially suitable for general practitioners. —Royal Free Hospital, Gray's Inn-road, W.C. Ante-natal demonstration by Prof. McIlroy. Wed., 5 P.M. (These courses are open only to Members of the Fellowship of Medicine.)

ST. PAUL'S HOSPITAL, Endell-street, W.C.

Wednesday, June 22nd.—4.30 P.M., Mr. C. H. Mills: Some Interesting Urological Cases, with demonstrations, specimens, and radiograms.

NATIONAL HOSPITAL, Queen-square, W.C.

Monday, June 20th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Head Injuries.

Tuesday.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Collier: Cerebral Tumours, their Symptoms and Localisation.

Wednesday.—2 P.M., Dr. Martin: Out-patient Clinic.

Thursday.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Pituitary Tumours.

Friday.—2 P.M., Dr. Adie: Out-Patient Clinic. 3.30 P.M., Dr. Symonds: Head Injuries.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, June 23rd.—4.30 P.M., Dr. J. K. Hasler: Methods of Anæsthesia in Rectal Surgery.

LONDON JEWISH HOSPITAL, Stepney Green, E.

Thursday, June 23rd.—4.15 P.M., Dr. D. Nabarro: Congenital Syphilis.

ST. PETER'S HOSPITAL, Henrietta-street, W.C.

Wednesday, June 22nd.—3 P.M., Mr. J. Alban Andrews: Injuries of the Urethra and their Treatment.

SOUTH WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Balham, S.W.

Wednesday, June 22nd.—4 P.M., Prof. E. C. Dodds: Biochemistry and the General Practitioner.

NATIONAL CENTRE AND POST-GRADUATE SCHOOL OF RADIOTHERAPY, Riding House-street, W.

Wednesday, June 22nd.—4.30 P.M., Mr. Roy Ward: Diseases of the Skin.

ROYAL NORTHERN GROUP OF HOSPITALS.

Wednesday, June 22nd.—3.15 P.M. (at Royal Chest Hospital, City-road), Dr. J. Maxwell: Lung Abscess.

Appointments

Cameron, E. H., M.B., Ch.B. Edin., F.R.C.S. Edin., has been appointed Ophthalmic Surgeon to the Edinburgh Royal Infirmary.

King's College Hospital: Lawrence, R. D., M.D. Aberd., Junior Physician in charge of the Diabetic Department; Cawthorne, Terence, F.R.C.S. Eng., Junior Surgeon in Ear, Nose and Throat Department.

London County Council: B. E. Moss, M.B., B.S. Lond., Temporary visiting medical officer, Edmonton Colony.

Certifying Surgeons under the Factory and Workshop Acts: Davies, D. H., L.R.C.P. Lond., M.R.C.S. (Rhondda, Porth, Glam.); Hadfield, R. H., L.R.C.P. Lond., M.R.C.S. (St. Just, Cornwall); Pettigrew, F., M.B., Ch.B. Glasg. (Wartle, Aberdeen); Sanderson, R. (Uffculme, Devon); and Wood, S., L.R.C.P. Lond., M.R.C.S. (Burnley, Lancs.).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Asst. M.O. for Radium Department.

Accrington, Victoria Hospital.—H.S. £150.

All Saints' Hospital for Genito-Urinary Diseases, Austral-street, West-square, S.E.—Two Hon. Anæsthetists.

Altrincham General Hospital.—Sen. and Jun. H.S. At rate of £150 and £120 respectively.

Banbury, Horton General Hospital.—Res. M.O. At rate of £150.

Bedford County Hospital.—Second H.S. At rate of £140.

Birkenhead County Borough.—Res. Asst. M.O. £350.

Birmingham, Erdington House.—Additional Asst. M.O. £650.

Blackburn Royal Infirmary.—Fourth H.S. £150.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £100.

Bristol General Hospital.—Sen. Res. M.O. £200.

British Empire Cancer Campaign, 12, Grosvenor-crescent, S.W.—William Morris Research Fellowship in Radiology. £500–£1000.

Burnley, Victoria Hospital.—H.P. and H.S. Each at rate of £150.

Buxton, Devonshire Hospital.—Asst. H.P. and H.S. Each at rate of £150.

Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist and Emergency Officer. At rate of £130.

Canterbury, Kent and Canterbury Hospital.—H.S. At rate of £125.

Cardiff, King Edward VII. Welsh National Memorial Assoc.—Area Asst. Tuberculosis Phys. £500.

Cardiff Royal Infirmary and City County Council.—Hon. Phys. and Visiting Phys. to Dept. of Children's Diseases. £100. Also Lecturer in Children's Diseases at Welsh National School of Medicine. £50.

Carlisle, Cumberland Infirmary.—Second H.S. £155.

Chorley Borough.—M.O.H. and School M.O. £800.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Gt. Barrow.—H.P. At rate of £100.

Colchester, Essex County Hospital.—H.P. Also Asst. H.S. £150 and £100 respectively.

Derby.—Locum Res. Asst. M.O. for Walton Sanatorium, near Chesterfield. At rate of £350.

Dewsbury and District General Infirmary.—Second H.S. £150.

Evelina Hospital for Sick Children, Southwark, S.E.—Hon. Phys. to Out-patients.

Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.

Guy's Hospital.—Sir Alfred Fripp Memorial Fellowship in Child Psychology. £300.

Hospital of St. John and St. Elizabeth, 60, Grove End Road, N.W.—Res. H.P. At rate of £100.

Huddersfield Royal Infirmary.—Cas. O. and Two H.S's. £225 and £150 respectively.

Hull Royal Infirmary.—H.P. at Sutton Branch Hospital. At rate of £160.

Ilford, King George Hospital.—H.S. At rate of £100.

Indian Medical Service.—Appointments Commission.

King Edward Memorial Hospital, Ealing.—Sen. Res. M.O. £250.

Lancaster County Mental Hospital.—Asst. M.O. £500.

Leicester Royal Infirmary.—Hon. Orthopædic Surg.

Lewisham Hospital, High-street, Lewisham, S.E.—H.P. At rate of £80.

Lincoln, Bracebridge Mental Hospital.—Second Asst. M.O. £425.

Liverpool, Alder Hey Children's Hospital.—Med. Supt. £1000.

Liverpool, Royal Children's Hospital.—Hon. Phys.

Liverpool, St. Paul's Eye Hospital.—H.S. At rate of £145.

London Clinic and Nursing Home Ltd, 20, Devonshire-place, W.—Res. M.O. At rate of £200.

London Light and Electrical Clinic, 42, Ranelagh-road, S.W.—Hon. Visiting Anæs. and Two Hon. Visiting Phys.

London Lock Hospital, 91, Dean-street, W.—H.S. to Male Lock Hospital. At rate of £175. Also Surg. Reg. At rate of £100.

London University.—Examinerships.

Llanelly and District Workmen's Medical Committee.—Surg. for Ear, Nose and Throat Dept.

Manchester, Ancoats Hospital.—H.P. At rate of £100.

Manchester Royal Infirmary.—Hon. Asst. Phys. Also Hon. Orthopædic Surgeon.

Middlesbrough, North Ormesby Hospital.—H.P. and H.S. At rate of £120 and £135 respectively.

Miller General Hospital, Greenwich-road, S.E.—Out-patient Officer. At rate of £150.

Norfolk County Council.—Temporary Asst. M.O. 10 guineas weekly.

North Western Fever Hospital, Lawn-road, Hampstead, N.W.—H.P. At rate of £80.

Norwich, Norfolk and Norwich Hospital.—H.S. to Special Depts. £120.

Nottingham General Hospital.—H.S. At rate of £150.

Oldham Royal Infirmary.—H.S. Also Cas. O. and H.P. Each at rate of £175.

Plymouth, Central Hospital.—Res. H.S. At rate of £150.

Princess Beatrice Hospital, Richmond-road, Earl's Court, S.W.—Cas. O. and H.P. £100.

Queen's Hospital for Children, Hackney-road, E.—H.S., H.P., and Cas. O. Each at rate of £100. Also Ophth. Surg.

Queen Mary's Hospital for the East End, E.—H.S. At rate of £120.

Reading, Royal Berkshire Hospital.—H.S. £150.

Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.

Royal Army Medical Corps.—25 Permanent Commissions.

Royal College of Physicians, Pall Mall, S.W.—Two Leverhulme Research Scholarships. Each £500.

Royal Free Hospital, Grays Inn road, W.C.—Res. Unit Anæs. £150. Also Clin. Assistantships in Special Depts.

Royal National Orthopædic Hospital, 234, Gt. Portland-street, W.—H.S. for Country Branch, Brockley Hill, Stanmore. At rate of £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

St. Mary Abbots Hospital, Marloes-road, W.—Res. Med. Supt. £1100.

St. Mary's Hospital for Women and Children, Plaistow, E.—Clin. Asst.

Salford Royal Hospital.—Cas. H.S.

Salisbury General Infirmary.—Two H.S's. Each £150.

Sheffield Children's Hospital.—Res. M.O. £175. Also H.P. and H.S. Each at rate of £100.

South London Hospital for Women, Clapham Common, S.W.—H.S. At rate of £100.

Southampton Children's Hospital and Dispensary for Women.—Res. M.O. At rate of £100.

Southampton, Royal South Hants and Southampton Hospital.—H.P. Two H.S's. and Cas. O. Each at rate of £150.

Stirling District Mental Hospital, Larbert.—Third Asst. M.O. £250.

Stockport Infirmary.—Jun. Res. Surg. £150.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Orthopædic H.S. £150. Also Asst. H.P. £125.

Tunbridge Wells and Counties General Hospital.—H.S. £160.

Walsall General Hospital.—H.S. At rate of £150.

West Bromwich, Hallam Hospital.—Sen. Res. M.O. £350. Also Two Res. H.P.'s. Each £200.

West Riding of Yorkshire County Council.—School Med. Inspector. £500.

West Suffolk County Council.—Asst. County M.O. and Asst. School M.O. £500.

Winchester, Royal Hampshire County Hospital.—H.S. At rate of £125.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E.—H.P. and H.S. Each at rate of £100.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Stow (Mid Lothian), Stromness (Orkney), and Bathgate (West Lothian).

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the Aylesbury and High Wycombe and Chesham County Court districts. Applications for the post should reach the Private Secretary, Home Office, Whitehall, London, S.W. not later than July 2nd.

Births, Marriages, and Deaths

BIRTHS.

Barnsley.—On June 7th, at Ellesmere, Salop, the wife of Dr. Arnold Barnsley (late of Singapore), of a daughter.

Bowers.—On June 11th, at Woodlands, Overstone Park, Northampton, the wife of Captain G. P. Farmar Bowers, I.M.S., of a daughter.

MARRIAGES.

Andrews—Henderson.—On June 1st, at Victoria Memorial Hall, Belfast, Charles T. Andrews, M.D., M.R.C.P., to Mabel L. V. Henderson, M.B., B.Ch.

Cookson—Mitchell.—On June 2nd, at St. Matthew's, Bayswater, Harold Cookson, M.D., to Elizabeth Mary, daughter of the late William Roger Mitchell and of Mrs. Mitchell, of West Kensington Mansions, W.

DEATHS.

Bannerman.—On June 10th, at St. Andrews-street, Cambridge, William Bannerman, M.B., C.M. Edin.

Harvey.—On June 10th, at a nursing home in London, Charles Edward McNiel Harvey, M.B. Edin., M.R.C.S., L.R.C.P Lond., of Beckford Lodge, Sar-la-Mar, Jamaica, aged 66.

Murray.—On June 11th, Herbert Leith Murray, Rodney-street, Liverpool, aged 52.

Seaman.—On June 12th, at Fernside, Hollington Park, St. Leonards-on-Sea, Albert Baird Seaman, Brig.-Surgeon Lt.-Colonel, I.M.S. (retired), aged 89.

Smith.—On June 4th, Hugh Smith, L.R.C.S., L.S.A., R.A.M.C., J.P., of Dixons Green, Dudley, aged 56.

Steele-Perkins.—On June 9th, suddenly, George Steele-Perkins, M.D., of The Arts Club, Dover-street, W., and of Kingsdown, near Deal, aged 75 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Sale of Saunderton Sanatorium.—Saunderton Sanatorium, near High Wycombe, has been sold by the governors of the City of London Hospital for Diseases of the Heart and Lungs to the Buckinghamshire county council for use as an isolation hospital. The hospital cannot continue to afford the expense of maintaining an independent country establishment, and patients will in future be sent from London to various convalescent homes by arrangement with the almoner.

NOTES, COMMENTS, AND ABSTRACTS

THE FIRST INTERNATIONAL CONGRESS ON ASTHMA

(FROM A CORRESPONDENT)

WITHIN the last few years research on asthma has received increasing attention throughout the world, and nowhere more than in England and Scotland since the formation of the Asthma Research Council five years ago. The time is fitting therefore for an international congress, and the meeting on June 4th–5th was successful not only because it set out divers views and interests, but also because it gave individual workers a chance of discussing problems with one another. Probably no better place could have been chosen than Mont Dore, "Providence des asthmatiques," whose associations with asthma date back even to Roman times.

The Scientific Sessions

The congress was held under the presidency of Prof. Fernand Bezançon, of Paris, and was attended by about 400 visitors, many of the medical men being accompanied by their wives and families. In his opening address Prof. Bezançon dealt with the Evolution of our Knowledge of Asthma, discussing the various ætiological theories that have held sway, and drawing particular attention to the pioneer researches of Widal and his co-workers.

The *nervous element* in asthma was discussed by Prof. P. L. Abrami and Dr. E. Bernard (Paris) and Prof. R. J. S. McDowall (London). Whilst the former speakers dealt with the production of bronchospasm through nervous channels either reflexly or through psychic stimuli, Prof. McDowall drew attention to the local production of bronchospasm through a liberation of histamine in the bronchi by numerous strains of gram-negative bacilli which Dr. F. A. Knott has described. Two interesting communications dealing with this aspect deserve mention. Dr. P. Dodel (Clermont-Ferrand) described the experimental production of asthmatic dyspnœa in animals by provoking a bronchitis with chlorine and then giving infinitesimal doses of pilocarpine which were without effect on normal animals. In its clinical application such work bears out the oft-observed fact that asthma has frequently followed lung affections and gassing during the war. Dr. J. André (Mont Dore) described some high creatinine values in the blood during attacks, and suggested creatinine estimations as a chemical test of the vagosympathetic tone in asthma, high values occurring with a state of vagotonia, low values with sympatheticotonia.

The rôle of *anaphylaxis and allergy* in the ætiology of asthma was ably discussed by Prof. Pasteur Vallery-Radot (Paris), who concluded that all asthma was not anaphylactic. Prof. C. Frugoni (Padua) described the production of asthma in normal children by the transference of blood from asthmatic sufferers. Prof. Storm van Leeuwen (Leyden) gave an interesting account of the various factors of soil and climate as they affect asthma in Holland, and of his methods of removing these "climate-allergens" by the use of allergen-proof chambers.

Local factors in the bronchi and nose, such as hypertrophy and infection, were dealt with by Dr. Haibe (Namur) and Prof. E. Halphen and Dr. H. Bourgeois (Paris). The indications for surgical intervention and the therapeutic value of vaccines were discussed, but the end-results of either were not very convincing. Dr. R. Leroux (Paris) described the characteristic formation of polypi in the nose and antra, and Dr. Bloch (Paris) the histological structure of these polyps, which included eosinophils and Charcot-Leyden crystals.

The importance of the study of asthma in *infancy and childhood* was stressed in the reports of Drs. Lesneé and G. Dreyfus-Sée (Paris) and Dr. Péhu (Lyons). The ætiology, symptoms, diagnosis, and treatment were discussed in full, and tallied largely with observations that have already been published in England. With regard to treatment, the children in France appear to get much more injection-therapy (specific allergens, vaccines, blood, milk or peptone) than seems necessary in England.

Hepatic insufficiency and *endocrine dysfunction* were suggested as important ætiological factors in asthma by Prof. V. Cordier (Lyons) and Dr. Léopold Lévi (Paris), whilst Dr. A. Schlemmer (Mont Dore) described the liver as being enlarged and tender to palpation in over half the cases he had seen. Though a large number of suggestions were made as to what function of the liver was at fault, and how it produced the asthmatic state, no conclusive proof was presented by liver function tests or controlled dietetic regulations of hepatic insufficiency. Most of the discussion on endocrines concerned the thyroid gland, since its function could be estimated by studies of the basal metabolism. Hypothyroidism was present much more frequently than hyperthyroidism, though both could be associated with the asthmatic state.

Probably one of the most interesting subdivisions for discussion was that of the *biochemical basis of asthma* and other allergic conditions, which was opened by Dr. G. H. Oriel (London). Dr. Epstein (Geneva) gave a very interesting communication on acid-base disequilibrium in asthma, and Dr. F. T. Harrington (Newcastle) discussed the important part played by the stomach, dyspepsia being a constant symptom in the majority of asthmatics. Dr. George Bray (London) outlined the importance of the hereditary factor in allergic conditions; it could be elicited, he said, in two-thirds of all cases, which no treatment known at present appeared to influence. Dr. Jacquelin (Paris) discussed the relative incidence of other allergic conditions in asthmatic patients and their families.

The last session dealt solely with *treatment*. Dr. E Joltrain (Paris) dealt with the general treatment of the asthmatic attack, whilst Dr. de Gennes (Paris) spoke on the treatment of the asthmatic individual. The subject was dealt with rather in text-book fashion in the opening papers, but the smaller communications were of great interest. Dr. Epstein (Geneva) dealt with attempts to treat the asthmatic by modifying his acid-base equilibrium towards the acid side; Dr. Brabant (Brussels) described a method of treating asthma by shock, and Dr. Pepère (Mont Dore) by blood-letting. Physical treatment by radiotherapy and actinotherapy seems to play a more important part in the treatment of asthma in France than elsewhere.

Treatment at Mont Dore.

Of great interest to the visitors was the account of the principles of treatment and the action of the waters of Mont Dore, given by the local physicians, Drs. Galup, Robert, and Bouchon. They restrict themselves to the therapeutic use of the waters and gases which are peculiar to the place, and do not, as a general rule, advocate treatment that can be obtained elsewhere. The visitors were conducted over the thermal establishment each morning in small groups by the various doctors of the station, and the various methods of "taking the waters" were described and seen. The waters are warm and quite pleasant to the taste, and the free gas is mildly stimulating to the nasal mucous membrane. They contain carbonic and hydrochloric acids in solution, with traces of silica, arsenic, and other metals. Ten to twenty minutes in the inhalation chambers leads to intense peripheral vasodilatation, and later to relief of an impending attack. The patients stated that inhalation was far superior to drinks or douches of the water, whilst nasal complaints were greatly alleviated by the nasal inhalation of the pure gas.

The English visitors included Prof. McDowall and Drs. Oriel and Bray (London), Dr. Harrington

(Newcastle), and Dr. H. H. Moll (Leeds). It was unfortunate that the German, Argentine, Spanish, American, and Rumanian representatives, after forwarding their contributions, were at the last moment unable to attend. All the opening papers were collected into book form in French before the congress, and may be obtained from Massón et Cie, Libraires de l'Académie de Médecine, 120, Boulevard Saint-Germain, Paris. The numerous interesting communications and discussions will be printed in a companion volume at a later date.

The social arrangements were excellent, and the physicians and the municipality of Mont Dore are to be congratulated on their organisation, munificence, and zeal.

IN DEFENCE OF EXPERIMENTAL RESEARCH

DURING the last few weeks two spirited attacks on those who would impede the progress of medicine have been delivered. Lord Moynihan, in an appendix to the Romanes lecture delivered in the Sheldonian Theatre at Oxford on June 1st, which has since been published in pamphlet form,[1] set out his position in the following words :—

> "Here let me frankly face criticism that has been directed against the methods of our laboratories, and has resulted in a most lamentable impediment to the advance of medicine. Without experiment on living animals, that advance, already greatly hampered, cannot continue. I recognise and endeavour to understand the motives which animate powerful bodies of noble and highly gifted men and women who are opposed to experimental methods. No right-minded man ever wishes to inflict suffering upon man or animal. That is abhorrent to us all. Opposition to animal research, I firmly believe, is based upon lack of appreciation and understanding ; as it is certainly supported by grievous and, I think, unpardonable misstatement. Day by day for many a year it has been my happy duty to operate on men, women, and children who now number a goodly company, in order to save life or bring relief. My heart is full of compassion. I cannot bear to cause or even to hear of suffering. Every one who has experience of laboratory work knows how little pain is inflicted, and what steps are always taken to minimise or abolish it. Yet the slight distress we must occasionally impose in our work upon man is greater in intensity, and far more protracted, than any suffered in our laboratories. It is simply not the truth to say that pain is wantonly, or unavoidably, inflicted there. The experimenter who excites suffering defeats his own aims : for pain changes the issues he seeks to discover. Physiologists and surgeons are the most humane of men. The necessities of their work would impose this quality if it were not already possessed. The whole anti-vivisection campaign, though a great testimony to the tenderness of heart of its supporters, has no slightest foundation in truth, and is a witness to their shut-mindedness and credulity."

In the sixth Stephen Paget lecture given to the Research Defence Society at the London School of Hygiene and Tropical Medicine on June 15th, Sir Arthur Keith, F.R.S., emphasised

THE MODERN CONFLICT BETWEEN SENTIMENT AND REASON

He spoke of the contrast between physical experiments, which evoked an intellectual response, and physiological experiments in which hearts as well as heads were challenged. Not all kinds of living matter exercised this power. Botanists were untroubled thereby, but experiments on sentient animal matter evoked feeling in the experimenter as well as in the onlooker. Herein lay a critical difference between experimental physics and experimental biology. The physicist had to satisfy only a single or scientific ideal ; the experimental biologist had to satisfy an ethical as well as a scientific standard. The conflict between sentiment and reason, as carried on to-day, found its sharpest expression in the opposition offered to the beneficial work carried on by experimental physiologists. The antivivisection crusade was only an acute manifestation of a conflict which permeated modern society—a conflict in which blind sentiment is ranged against clear reason. Minor manifestations of the same conflict were met in all departments of medicine. Every medical measure which aimed at an ultimate cure by the infliction of immediate suffering entailed a repression of feeling on the part of the prescribing physician. The judge on the bench had to divest himself of his natural instincts if he was to administer law to the criminal in the dock. The crowd, bemoaning the terrible end that awaited the man in the condemned cell forgot the justice due to the woman whom the criminal had widowed. No parent ever administered punishment to a child, however deserved and salutary the punishment might be, without a conflict between reason and sentiment. There was a growing feeling amongst teachers that physical punishment, administered to scholars, was an unjustifiable form of cruelty. Sentiment asserted itself more and more as a ruling force. The repugnance to eugenical measures of a surgical nature sprang from sentiment, not from reason. Amongst all highly civilised peoples there was a growing tendency for feelings to dominate reason and for sentiment to be accepted as a guide in life rather than intellect. These changes were vaunted as sure signs of human progress. If sentiment and feeling were to subjugate and enslave reason—as now they threatened to do—then the ultimate result for civilisation would be, not progress—but disaster. The conflict in which the members of the Research Defence Society were now engaged was not merely to vindicate the right of medical men to carry out inquiries which were lawful under the Act of 1876, but also to demand that in settling all issues relating to the life and death of a community reason as well as sentiment must have a say in the decision.

DRESS REFORM FOR THE MALE

AN association named the Men's Dress Reform Party has issued a notice, "to those whom it may concern," of a dinner, at which a debate on dress reform for men has been arranged. The dinner will take place at the May Fair Hotel, London, on Friday, June 24th, and early requests for tickets should, it is suggested, be made to Dr. A. C. Jordan, 82z, Portland-place, London, W., who is acting as honorary secretary. The price of tickets for men and women alike is 12s. 6d., exclusive of wine. The notice claims that the party will be "the sartorial event of the London season," and, with regard to the male attire thereat, we are informed that men may "adopt healthy and decorative styles in accordance with their fancies," while the less adventurous may appear in a dinner jacket. Dr. C. W. Saleeby will act as chairman of the ensuing debate, when a motion will be put forward by Mr. C. E. M. Joad and seconded by Dr. Haden Guest, that "Man must be Redressed." The motion will be opposed by Mr. D. Anthony Bradley, and it is hoped that among the leading speakers will be Canon Percy Dearmer and Mr. Ernest Thesiger.

JEAN ATHERTON

WE are informed that Jean Atherton, alias Mary Beale, alias Millicent Aldridge, was sentenced as "the most persistent begging-letter writer in the country" to 18 months' imprisonment at the recent London Sessions. We have made allusions in these columns to her methods, because, on the plea that she was the daughter of a "Dr. Thomas Beale," she made frequent appeals to the medical profession, who, therefore, might find a warning useful.

HOSPITAL FINANCES AT HASTINGS.—The Royal East Sussex Hospital is tackling its financial situation efficiently, and at the annual meeting it was stated that the excess of expenditure over income was only £902 as compared with £2414 the previous year. The average cost per week per patient fell to £2 17s. 2·28d. from £3 2s. 2·23d., while £549 was received in respect of street accidents, leaving a deficit of £904 to be found out of the hospital's ordinary income. Attendances of both in-patients and out-patients increased.

ADDRESSES AND ORIGINAL ARTICLES

THE REACTIONS OF THE EYE TO GENERAL DISEASE*

By F. A. Williamson-Noble, M.B. Camb.,
F.R.C.S. Eng.

ASSISTANT OPHTHALMIC SURGEON TO ST. MARY'S HOSPITAL, AND TO THE NATIONAL HOSPITAL, QUEEN-SQUARE; ASSISTANT SURGEON TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL

Reactions of the Lens to General Disease

The lens has several peculiarities; it continues to grow throughout life, it has no blood-supply, and it has an auto-oxidation system of its own. This system is interesting and is probably effected through a sulphur-containing amino-acid known as cysteine which on oxidation yields cystine, the process being reversible (as a hydrogen atom is replaced by one of sulphur). In the lens these acids are probably combined with glutamic acid, in a form known as glutathione, and the presence of this substance seems to be essential to the proper functioning of the lens, since it is absent in cataract.[1] It probably acts as a carrier of oxygen in much the same way as does hæmoglobin.

The first disease which occurs to one in connexion with the lens is, of course, diabetes, with its well-known complication of diabetic cataract. There is another complication, however, which is quite common though not so well known, and that is alteration in the refractive index of the lens. This is of great clinical importance; what probably happens is that, as a result of alteration in the osmotic pressure of the eye fluids, accompanying the rising sugar concentration in the blood, fluid tends to enter the lens. This makes it bulge, increases its convexity, and so renders the eye more myopic, a change which may take place without any development of cataract.

I have myself seen as much as 20 dioptres of myopia develop in the course of diabetes. The converse may also occur with sudden decrease of sugar, and Duke-Elder[2] records a case in which 6 dioptres of hypermetropia and a marked change in astigmatism developed after three days of vigorous insulin treatment. The importance of this is that, if one is guided by the vision alone, quite a false impression may be created as to the usefulness of the eye.

My old lady, for example, who developed her 20 dioptres of myopia had also a little cataract, and if one had been content to estimate her visual powers by what she could see with glasses ordered six months previously, one would have assumed that she needed a cataract extraction, whereas all that she needed really was the addition of 5 dioptres or so to her last correction in order to obtain useful vision again.

Duke-Elder's case was more dramatic, since the patient complained of blindness, though vision with correction of the acquired hypermetropia was 6/9 in one eye and 6/12 in the other.

Mr. Percy Fleming tells an amusing story concerning a diabetic patient aged about 47. When he was dieting and playing the game, he was emmetropic, and required glasses for presbyopia. If, however, he let himself go, and indulged a passion he had for eating sweets, his eyes became sufficiently myopic to enable him to read without glasses. All one had to do, therefore, to see whether he was sugar-free or not, was to ask him to read. If he put on his glasses he was sugar-free; if not, he was glycosuric.

The moral of all this is that if visual acuity is to be taken as the criterion of utility of the eyes in a case of diabetes, an accurate determination of the refraction must first be made. A useful tip, in cases where this cannot be done, is to take the patient's vision when he is looking through a stenopæic hole. The process is very simple; all that is necessary is to make a pin-hole through a piece of cardboard and ask the patient to look through it. If his vision is improved appreciably, it is almost certain that an error of refraction is present.

Tetany and dystrophia myotonica are two other diseases associated with cataract. Both of these are rare, but tetany is interesting because it was thought to throw a light on the pathogenesis of senile cataract. Calcium deficiency is a characteristic of the disease, and it has been proved fairly conclusively that this is also the cause of the cataract associated with it. Kirby,[3] experimenting on embryo chick lenses in tissue culture, found that the cells would stand relatively large increases in the calcium content of the culture medium without showing any great differences in appearance, growth, or activity. On the other hand, relatively slight reductions of the calcium content of the medium produced toxic reactions in the cells. Such an observation immediately suggests calcium deficiency as a cause of senile cataract, and therefore parathyroid administration as a means of treatment. Dorothy Adams,[4] however, found that the lenses removed for senile cataract actually contained a higher percentage of calcium than normal ones, and that the serum calcium was also higher, so, although calcium deficiency is a cause of a tetany or a parathyroid cataract, it does not seem to be the cause of the senile variety. In all probability the calcium increase in the latter is merely an indication of loss of function of the lens capsule, since this membrane, when in a healthy condition, acts as a semi-permeable one and has a remarkable power of allowing potassium to enter the lens and of excluding all but a small proportion of the calcium.

Dystrophia myotonica is chiefly of interest from the hereditary point of view. Fleischer, in his classical report published in 1918, described a number of instances of myotonic dystrophy among his cases of presenile cataract. An interesting observation made by Knusel is that post-operative cataract following accidental parathyroidectomy is nearly identical with that developing in muscular dystrophy. It is possible, therefore, that the latter disease is attributable to parathyroid insufficiency.

Tuberculosis

In opening a discussion on ocular tuberculosis three years ago Dr. R. A. Young[5] said:

> "It is a significant and healthy sign of the times that in both medicine and surgery we are becoming more catholic in our outlook, and realising that co-operation is better than purely departmental discussion, especially in difficult matters arising in the border zones of our respective fields of work."

In this subject I am on the borderline between ophthalmology and general medicine, and it is not difficult to stray too far over that line. It has, in fact, been my object in preparing these lectures to sit, so to speak, on the hedge between general medicine and ophthalmology, or—to put it another way—to convert what might be regarded as a no-man's-land between these two departments into an everyman's land.

The importance of tuberculous infection in the ætiology of eye disease is becoming more and more evident, and, except possibly in the conjunctiva, the infection is blood-borne; therefore the portion of the eye most commonly affected is that which is most richly supplied with blood-vessels—namely, the uveal tract, comprising the iris, ciliary body, and choroid.

---

* The second Lettsomian lecture for 1932, delivered before the Medical Society of London on March 7th. The first lecture appeared last week, and the third lecture will appear in a coming issue.

The classical descriptions of the reactions of the uveal tract to the tubercle bacillus are familiar but are worth recalling with a few additions to the ordinary text-book varieties. The two forms of tuberculosis, miliary and confluent or conglomerate, may occur in the eye in the same way as they do in other parts of the body, but there are also other varieties. Finoff[6] describes four different types in the iris. The first is a diffuse infection which may be so acute in onset as to resemble other types of iritis, though more usually it is gradual and painless. Nodules generally appear later in the iris stroma and make the diagnosis clear. Also the deposit of inflammatory products on the back of the cornea occurs in a characteristic manner, forming relatively large, unpigmented spots, supposed to resemble mutton-fat and therefore called "mutton-fat K.P." The second variety is the miliary, where nodules in the iris are generally greyish-red or yellow in colour and develop at the margin of the pupil or its ciliary border without preceding iritis, these nodules being 2–3 mm. in diameter. They may undergo absorption or spread, involve the cornea, and lead to perforation of the globe at the corneo-scleral junction with subsequent shrinkage of the eye. This form of lesion, when progressive, is most commonly associated with diffuse miliary tuberculosis and involves the whole uveal tract, the patient often dying before the disease has had time to run its full course in the eye. Hæmorrhages into the anterior chamber often occur in this variety of the disease.

In the third type, the conglomerate form, a yellowish nodule grows, usually from the periphery of the iris, covered sometimes with smaller nodules, and steadily increases in size, until the globe is perforated. These nodules are sometimes mistaken for malignant growths. The ciliary body may become infected without involvement of the other parts of the uveal tract, but in this stage the infection is usually overlooked because so few signs and symptoms are produced. The condition is of importance from a purely ophthalmic point of view, however, because it may frequently form the starting-point for other forms of ocular tuberculosis, extension occurring either forwards or backwards. In the early stages the only sign may be the presence of some mutton-fat deposit on the back of the cornea.

When the choroid becomes involved, the lesion again may be of the miliary or conglomerate type, or it may simulate the disseminated variety commonly produced by syphilis. Miliary tubercles of the choroid have a special importance in the diagnosis of tuberculous meningitis. They appear as small grey or yellowish, round or oval spots near the posterior pole of the eyeball. Their size varies from one-half to one-third of a disc diameter and they are slightly elevated, so that the retinal vessels bulge as they pass over them. Their appearance usually marks a terminal stage in the disease, so that little change occurs in the ophthalmoscopic appearances but, should the patient survive, the affected areas cicatrise, leaving brilliantly white spots with a margin of dark pigment.

It is important to realise that there is another form of miliary tuberculosis of the choroid which has not the same gloomy prognostic import so far as life is concerned, though the affected eye is frequently lost from glaucoma, secondary to the accompanying cyclitis. The occurrence of this cyclitis is an aid in the diagnosis, as is also the fact that the tubercles are not always localised to the posterior pole of the eye, but may be seen also in the periphery and are frequently present in one eye only.

Conglomerate tuberculosis of the choroid is uncommon disease and scarcely needs descriptio since the name almost explains itself, the lesion co sisting of a large single nodule which may resemble intra-ocular tumour.

Of great interest, to my mind, is the question how and why the eye should react in the way it do to the presence of the tubercle bacillus. The first poi brought out by investigation is that the eye does n always react in the classical way. This, of course, disappointing but not unexpected: Urbanek, Vienna, investigated in detail 500 cases of uveitis di to tuberculosis and reported the results in a compr hensive monograph. The diagnosis was supported X ray examinations of the chest, by transmission tuberculosis to animals from the blood of patients wh the eye was at the height of a relapse, and by t response to a tuberculin, though this last test is n a reliable one, if Sir Almroth Wright's work on t non-specific immunising effect of tuberculin is to accepted. Urbanek's conclusion is an important one namely, that there is no typical clinical or pathologic picture that indicates a tuberculous process in the Even the slit-lamp and corneal microscope were not be relied upon, and every type of iritis could mimicked by the tuberculous form. Gonococcal iriti as I have already mentioned, has long been regarde as a clinical entity and in the majority of cases is s yet Urbanek states that the typical gelatinous cond tion of the aqueous may occur in a purely tuberculo infection. The commonest type of lesion is benig not associated with any of the disastrous sequel such as perforation of the globe and general dissemin tion of tuberculosis, which occur in the so-calle classical forms. The reason for this, I hope to sta presently, and also the reason why tuberculin, so litt used in disease of other parts of the body, appears give such good results in ophthalmology. I we remember Dr. R. A. Young, in the discussion to whic I have already alluded, telling us the dangers of th reagent in the pulmonary forms of tuberculous disea and of its relative safety—if given intelligently— the surgical varieties of tuberculosis.

It is a great pity that tuberculous infection of th uveal tract should not always show definite pathogn monic changes, because the area affected is in man cases so minute that if any other organ were involve it would probably cause no symptoms beyond sligh general malaise, whereas in the eye the effects a apparent at once—i.e., we probably get, quite ofte in the eyes an early indication of tuberculosis whic may be of great clinical importance but may easily overlooked. Time in these cases is, so to speak, th essence of the contract, and the sooner the diagnos is made and the patient is brought under the influenc of treatment, the greater the chance of ultimat recovery.

ALLERGY IN OPHTHALMIC TUBERCULOSIS

A vast amount of work has been done on the reaso why the eyes develop these changes in the presenc of the tubercle bacillus, and one of the most interestin accounts of it is given by Rich and McCordock. In the first place they draw a distinction betwee immunity and allergy; the former is a reaction whic leads to the death of the bacilli and, if they are a killed, to the cure of the disease. Unfortunately however, when the bacillus dies, the proteins which i contains are liberated, and if the patient is allergic the cause various reactions according to the sensitivit of the patient and the amount of protein liberated If the patient is not allergic, nothing happens, but if h is, the relatively bland products of the breakdown o ubercle bacilli are converted into powerful irritants nd poisons without any apparent gain to the organism in the way of immunity. Tissue necrosis is regarded by these workers as being almost entirely the result of allergic hypersensitiveness to tuberculo-protein, hough the formation of tubercles does not appear to be a reaction of this type. This was shown by the observations that the formation of tubercles can be brought about by a lipoid extracted from the bacillus, which lipoid does not of itself produce any allergic changes. For the production of allergy it is necessary to use whole bacilli, and it appears that it has not yet been possible to extract from them the true sensitising antigen. A striking example of the bad effects of allergy was given by some tissue culture experiments performed by Rich and Lewis.[8]

> They placed thoroughly washed blood-cells and fixed connective tissue cells of allergic and normal guinea-pigs in the plasma of the normal and allergic animals. The same amount of tuberculin was then added to all the cultures. The cells from the allergic animals were regularly and promptly killed when exposed to tuberculin, regardless of the plasma in which they were placed, while the cells from the normal animals, regardless of the plasma in which they were placed, remained alive and multiplied when exposed to the same concentration of tuberculin which rapidly killed the allergic cells.

Allergy therefore seems to be a very real thing, and its occurrence accounts for the mild attacks of what would clinically be termed non-tuberculous iritis. It is conceivable, for example, that a healed focus of old tuberculosis may light up as a result of extreme exhaustion. The tubercle bacilli are disintegrated, as the patient has acquired immunity, but in their disintegration they set free tuberculo-protein. Unfortunately the patient is also allergic and therefore develops the so-called tuberculide iritis.

It appears from these observations that tuberculous disease of the eye is probably a good deal commoner than most ophthalmologists imagine and that, far from being the malignant and destructive type of lesion usually described, it may assume relatively benign forms. Moreover, some cases may not be due to actual lodgment of tubercle bacilli, but may merely represent the allergic reaction of the eye to the presence of tuberculo-protein in the blood. Though such an hypothesis has not yet met with universal acceptance, there is no question in my mind that a number of cases of obstinate infection of the uveal tract and of the cornea do better with tuberculin than with any other form of treatment.

THE RETINAL VESSELS

Before finally leaving this (to me) fascinating branch of ophthalmology there is one other point I should like to mention, and that is the occurrence of tuberculous disease of the retinal vessels. Eales first described the syndrome of recurrent vitreous hæmorrhages in apparently healthy young patients, a condition ascribed in many cases to tuberculous perivasculitis, eating away the vessel wall and allowing the escape of blood. Histologically, the perivascular infiltrates often contain large numbers of epithelioid cells, but since the same type of infiltrates can be produced in animals by repeated injections of blood into the vitreous, their presence does not prove a tuberculous ætiology.

High Blood Pressure

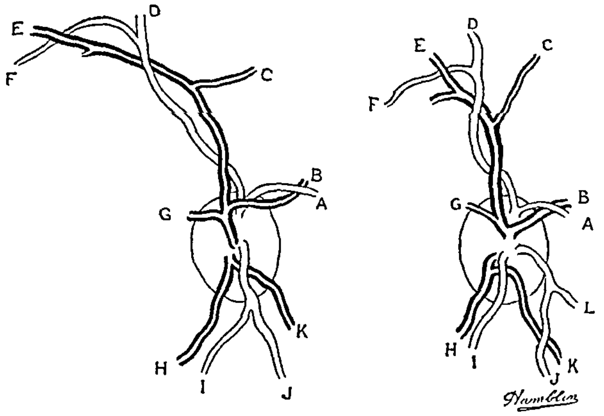
The changes in the eye associated with high blood pressure are of great clinical importance. In the first place, the retina is morphologically a portion of the brain and, from the clinical standpoint, it is the condition of the cerebral circulation which most closely concerns us in cases of vascular disease. Foster Moore[9] has found that as many as 70 per cent. of cases of gross cerebral vascular lesions show signs of retinal arterial degeneration, and, conversely, that 44 per cent. of cases showing ophthalmoscopic signs of vascular disease develop gross vascular lesions within a period of seven years. In the second place, the eye is the only portion of the body where the cerebral vessels are, so to speak, open to inspection and the dioptric arrangements are such as not only to render the vessels visible, but actually to magnify them 14 diameters. It is not surprising, therefore, that the ophthalmologist, by his routine examination of the fundus, is often the first person to discover the presence of vascular disease. An enormous literature has grown up recently around this subject, and, by way of clearing the ground, it will perhaps be best to follow the example of Friedenwald[10] and review the changes observed in the vessels.

VARIATION IN CALIBRE

The retinal circulation is a little unusual in that the larger vessels, although morphologically arteries, resemble arterioles in the thinness of their walls and the paucity of their muscular layer. The first and most important change, to my mind, is localised variation in calibre. The condition is not by any means conspicuous and, unless carefully sought, may easily be overlooked. One is apt to think, from reading descriptions of cases, that deformation of the veins at the arteriovenous crossings is a sine qua non of retinal arteriosclerosis, but I have seen quite definite nipping of the superior temporal vein by the artery in perfectly healthy children, and I have seen no nipping at all in cases where the systolic blood pressure was over 200 mm. Hg. There was, however, a tell-tale diminution in calibre of the inferior nasal and the superior temporal arteries. Mylius[11] is inclined to attribute some of the localised constrictions to a spastic contraction of the arterial wall, but the majority of authors consider the condition to be atheromatous and to be an extension of a similar process affecting, in greater degree, the central retinal vessels in the nerve. Moreover, atheromatous plaques can be found in the affected vessels post mortem by suitable staining methods. Whatever the explanation, there can be no question of the great clinical importance of the sign, in spite of its relative inconspicuousness.

In addition to the localised variations in calibre of the retinal arteries, there is often a generalised attenuation. The vessels so affected are often straight, instead of being curved, as in the normal eye, and usually give off their branches at an acute angle. One would expect this attenuation to be due to thinning of the blood stream, consequent on thickening of the vessel wall and cicatricial contraction of the artery, but such is not the case, histological examination failing to reveal any evidence of such a change. In fact these attenuated vessels are often found to have walls which are thinned rather than thickened. Friedenwald[10] adduces a very interesting theory to account for the condition. The arteries contract, not only in diameter but also in length, and this change can be well shown by figures (see p. 1348) reproduced from his article. They show the changes occurring in the vessels after the lapse of 15 years in a case of retinitis associated with massive exudation. The arteries are drawn in thin lines and the veins in thick ones. It appears as though all the superior temporal vessels had been pulled upward and outward, but the inferior vessels show an even more marked change. In 1914 the two main branches emerged separately from the disc, whereas in 1929 the junction of the two vessels *i* and *j* had been pulled down about one and a half disc-diameters. Presumably in this case the portion of the artery in the distal end of the nerve was not sclerosed, and was therefore capable of extension.

Another observation which fits in with this was made many years ago by Marcus Gunn. Small petechial hæmorrhages are not uncommon in retinal arterio-sclerosis, and careful examination will sometimes disclose the presence of a minute curved arterial twig, just near the hæmorrhage. Gunn's explanation was to liken the artery under tension to a hair drawn between the thumb-nail and forefinger—the hair curls up—and to say that the hæmorrhage represented the point where the artery had become detached from the retina. In the case quoted by Friedenwald the lesion was primarily in the retinal vessels, the condition being a rare one known as massive exudative retinitis. In some varieties of arterio-sclerosis, however, the central retinal vessels are probably affected even more severely during their neural than during their retinal course, and the result of this is that a sort of tug-of-war ensues, in which the neural vessels quite frequently prevail. For this reason one often finds more arterial branches crossing the edge of the disc in cases of sclerosis than in cases with normal fundi, the inference being that the vessels have become, so to speak, sucked into the disc. It is not surprising, therefore, that the retinal arteries should, in this disease, follow the Euclidean rather than the Einsteinian conception of a straight line and that the branches should be given off at acute angles.



Shows changes in the retinal vessels after 15 years. The drawing on the right shows the condition in 1914; that on the left in 1929. (Friedenwald.)

THE ARTERIAL LIGHT REFLEX

The second point to notice is the condition of the arterial light reflex. This is rather a trap for the unwary, since its brightness depends on the type of ophthalmoscope used, the size of the patient's pupil, and the general pigmentation of the fundus. A bright reflex is therefore of clinical value only when it is intense, when it varies greatly in different branches of the arteries, and when it is associated with other pathological changes. Irregularity of the reflex with beading is, of course, of value, since it indicates alterations in the arterial calibre.

THE ARTERIO-VENOUS CROSSINGS

The phenomena at the arterio-venous crossings again may be fallacious, since it is not impossible to have definite compression of the vein by the crossing of a perfectly healthy artery. Why this should be so, I do not know, unless it be caused by undue softness of the venous wall, and possibly by some distension of the vein itself. Nipping of the vein per s is not therefore sufficient grounds for the diagnos of retinal arterio-sclerosis and, since the sclerosis essentially patchy and may not affect the portion artery crossing the vein, its absence is also of no grea significance.

There are two other points which may help in th diagnosis of pathological changes at the arterio-venou crossings. The first is the presence of white lines alon the sides of the artery. In its extreme form this i known as pipe-stem sheathing and is due to perivascu litis, the artery being bordered by thick white line which may meet over the vessel's anterior surface s as to hide it completely. In its minor form these line are nothing like so conspicuous, but against the back ground of the vein at the point of crossing a definit white line may be detected on each side of the arter It is important not to confuse these with the whit lines which sometimes border the arteries during short part of their course from the disc, since the latte are physiological, being due merely to an extension o *the fibrous tissue of the disc.*

The second point concerns the distortion of the vein A healthy artery will usually cross the vein at an acut angle, without any alteration in the course of the latte In disease, however, the vein may often be twisted s as to allow the vein to cross under the artery as nearl as possible at right angles. The same phenomeno may occur when the vein crosses in front of th artery, and should this change be found, there nee be no doubt of the pathological condition of the vessel Loss of translucency of the artery at the crossing i another point which sometimes helps in diagnosis but it is not easy to estimate its degree.

The condition of the small vessels passing to th macula may be of great importance in cases o arteriolar sclerosis. In fact, in some cases of vascula disease of the most serious type these may be the onl vessels showing any visible change. In parentheses it may be noted that, in order to see them, it is usuall necessary to employ a mydriatic, and that in ol people, when resultant glaucoma may be feared, tw drops of 5 per cent. cocaine instilled at five-minut intervals will often produce a useful mydriasis i 30 or 45 minutes. The changes observed in thes vessels are an alteration in their course, whereb they become corkscrew-like, and an increase in th brightness of their reflex, which renders them lik silver wire.

The veins seldom show sclerotic changes except in the advanced cases. Sometimes they may be bordered by white streaks, but in most cases these are due to the presence of wandering cells carrying off detritus from retinal degeneration, secondary to arterial disease.

Classification of Vascular Anomalies

Having described the various changes which are observable in the retinal vascular system, I should now like to sort them out a little. Many attempts have been made to group these cases, and the latest and best, to my mind, is that adopted by Friedenwald, who defines six groups, of which we need consider only four, as the last two comprise syphilitic arterial disease and arterio-sclerosis depending on local disease in the eye.

The first group is *hyperpiesis without retinal arterio-sclerosis*, and comprises cases of great clinical diversity, such as acute nephritis, mild toxæmias of pregnancy, and hyperthyroidism.

The second group is *retinal arteriolar sclerosis*, and is important because all the cases which could be followed over a sufficiently long period developed renal (albuminuric) retinitis, and clinically they were all associated with very high blood pressure. In the early stages the changes found comprise those I have already described in connexion with the small arteries in the macular region—irregular tortuosity, localised variations in calibre, and visibility of the walls. The large arteries may be full and tortuous and usually compress the veins markedly. Although this type of fundus change is followed by renal retinitis, anatomical investigations have failed to show any close association between it and the arteriolar sclerosis of the renal blood-vessels.

The third type is *retinal arterio-sclerosis with hypertension*. The principal feature of these cases is reduction in calibre and length of all the arteries, which therefore take a straight course and branch at acute angles. Associated with this change there are usually arterio-venous compressions and local variations in calibre. Clinically these changes are usually associated with arterio-sclerosis of a slowly progressive type in elderly patients, though they may occur in younger people, when the prognosis is correspondingly more grave. If the condition persists for long, it may go on to the production of a type of retinitis.

The fourth group is *retinal arterio-sclerosis without hypertension*, in which the fundus picture shows arterio-venous compression, variations of calibre, and visibility of vessel walls, but the main arterial branches are full and tortuous. There may also be scattered hæmorrhages and retinitis. The prognosis in these cases is rather doubtful, as the vascular lesions have an uneven distribution, but in general they show little renal involvement. The prognosis in young people is of course more grave.

If sclerosis should persist in the retinal arteries over a period of years, the retina itself may begin to show changes and develop a so-called retinitis. This term is not of course pathologically correct, since the tissues of the retina do not undergo any inflammatory changes, but it has a convenient clinical significance and is therefore retained for that reason. Histologically, the change consists in the formation of hyaline nodules in the outer molecular layer of the retina. These nodules are visible with the ophthalmoscope as bright, white dots, seldom larger in diameter than one of the main veins. They are usually grouped at the posterior pole of the eye, and may occasionally form a star or a fan-shaped figure round the macula. Foster Moore[12] has noted that, though they are very slow to undergo change, the individual spots may in the course of time disappear, but that others develop and so the general appearance of the fundus remains the same. There are also, of course, hæmorrhages.

Foster Moore has undoubtedly performed a very useful piece of work in differentiating this type of retinitis from the so-called albuminuric or renal variety. The importance lies in the prognosis with regard to life because, although it is unusual for patients with renal retinitis to survive for longer than two years after the discovery of the lesion, patients with arterio-sclerotic retinitis may live quite a number of years, even though there may be some albumin in the urine from associated sclerosis of the renal vessels.

Albuminuric Retinitis

It seems appropriate now to say something about that vexed question of renal or albuminuric retinitis. First of all, what are the facts, so far as we know them? I hope you will not consider it old-fashioned if I refer to the varieties of nephritis as acute, chronic parenchymatous, and chronic interstitial. If we accept this classification, the last type of kidney disease is that in which retinitis is far and away the most common, while it is seen only rarely in association with the chronic parenchymatous form, and hardly ever in acute nephritis. Another fact in connexion with renal retinitis is that it is practically always associated with a raised blood pressure. Thus Foster Moore,[12] in examining 68 cases of nephritis, found that in 23 of them who had retinitis the average systolic blood pressure was 211 mm. Hg, and that in only six cases was it less than 200. Of the remaining 45 cases, who had no retinitis, the average systolic blood pressure was 150 mm. Hg, and in nine only did it exceed 160 mm. Hg.

The main ophthalmoscopic features are the soft-edged cotton-wool patches, the development of a star figure at the macula, the presence of hæmorrhages, and the occurrence sometimes of papillœdema. How are we to explain these features? It seems to me that we have three separate factors. In the first place, many cases of chronic renal disease suffer from increased intracranial pressure, and it is just those cases showing signs of this (excruciating headaches, transitory amaurosis, Cheyne-Stokes breathing, &c.) which develop œdema of the optic disc, the mechanism being presumably the same as that which accounts for the condition occurring in cerebral tumours: Larson,[13] for example, in 1924 reported 11 cases of renal retinitis, with an average spinal fluid pressure of 347 mm., in all of which there was marked papillœdema. Once we admit production of papillœdema from the mechanical effects of increased intracranial pressure, we have an explanation for the production of hæmorrhages and soft white areas in the region of the disc and for blurring and swelling of the disc itself.

The next factor is œdema of the retina, which in all probability is responsible for the star figure at the macula. In cases of cerebral tumour where there is a rapid rise of intracranial pressure it is not uncommon for a fan figure to develop, consisting of lines radiating from the macula towards the disc. In these cases it is the portion of retina between the disc and the macula which is œdematous, and it is here, therefore, that the radiating lines are seen. I have observed a similar condition in a case of thrombosis of the superior temporal vein where a fan figure formed, with the lines pointing upwards towards the area of retina rendered œdematous by blocking of the vein. In renal retinitis, however, the area of retina all round the macula is œdematous, and so the lines point out in all directions, making a complete star figure.

The third factor is probably the presence of some hypothetical toxic substance in the blood, which poisons the retina and gives rise to the formation of the cotton-wool patches. It is of course more than likely that the same substance is responsible for the œdema, since it is probably endotheliotoxic and, by its action on the capillary walls, renders them pervious to fluid and, in places, to blood also, thus accounting for the hæmorrhages. The pros and cons of this toxic theory have been hotly debated, and each side seems at first sight to have an almost unanswerable argument. Those in favour of the toxic theory point out that typical examples of renal retinitis may occur in the toxæmias of pregnancy where there is no associated general arterio-sclerosis, while those who regard arterio-sclerosis as the determining factor point to the absence of retinal changes in cases of profound renal insufficiency such as occurs in urinary obstructions. The answer to the first statement is that high blood pressure is prominently associated with pregnancy toxæmia, as is also œdema of organs other than the eye, and the answer to the second statement is that renal retinitis takes some time to develop and a patient with urinary obstruction is scarcely likely to live long enough for this to occur, at any rate if the obstruction is sufficient to cause retention of products of metabolism.

There remains, however, the factor of vascular disease to be accounted for. According to many authors, this is a sine qua non of renal retinitis. I have already quoted Foster Moore's figures which showed that in a series of cases of nephritis those which developed retinitis had a considerably higher blood pressure. I have also mentioned Friedenwald's statement to the effect that one particular type of retinal arterio-sclerosis, namely, the arteriolar variety, is invariably followed by renal retinitis and that, in addition, all cases of renal retinitis which he examined showed arteriolar changes, both by ophthalmoscopic and by histological examination. It does not seem to me, however, that such findings justify the assumption that sclerosis of the retinal arterioles is the cause of the retinitis, any more than because two certain things happen together one is necessarily the cause of the other. I would rather try to trace the matter further back and say that both have a common cause, and the line of argument would seem to be as follows: when the agent, whatever it is, that causes arterio-sclerosis affects the larger vessels, no retinitis of the albuminuric type is seen. The nearer the affection comes to the capillaries, however, the more likely are retinal changes. Now the arterioles in the region of the macula represent the smallest vessels which are visible in detail with the ophthalmoscope. Is it not possible, therefore, that we are dealing primarily with a toxic substance which has an elective affinity for the smaller arterioles, bringing about their sclerosis, and for the capillaries altering the permeability of their walls and so permitting the transudation of fluid and the occurrence of retinal œdema? If retinal œdema occurs, something of the same kind happens in the brain, bringing about a rise of intracranial pressure and papillœdema with its associated changes.

Diabetic Retinitis

Diabetic retinitis is an interesting condition which has excited a considerable amount of discussion, because it does not owe its origin to diabetes alone. Age plays its part, and retinitis is not seen in diabetics under middle life, although in such people diabetes may often assume its most malignant form. In spite of this, however, diabetic retinitis often assumes a form sufficiently characteristic to allow of ophthalmoscopic diagnosis. The hæmorrhages are for the most part small and circular, owing to their situation in the deeper layers of the retina. There are no cotton-wool patches, and the white areas present have a soapy appearance with clean-cut edges. Sometimes they are arranged in a circle round the macula. Finally, there is no retinal œdema to speak of and there is no star figure. The latter is sometimes seen but, even if it appears, it has not the regular pattern characteristic of the renal type of disease.

The causation is still a matter for discussion. The fact that diabetic retinitis does not occur in the young suggests that its development may be associated with vascular disease, and this is so in a fair proportion of cases, but not by any means in all. The same is true of albuminuria, which may or may not be present. It appears, therefore, that arterio-sclerosis and renal disease are concomitant, possibly contributory, but not causative of this form of retinitis. Another interesting feature of the condition is that it may occur in those who have had diabetes and are now sugar-fr or, to put it another way, that treatment directe towards curing the diabetes does not necessarily sto the retinitis. The essential lesion in the disease h seemed to me to be the recurrence of the deep-seate retinal hæmorrhages. In the hope of preventing thes I have at times tried empirically the administratio of calcium, sometimes with parathyroid, partic larly as it seemed possible that the white areas migl represent the results of organisation of the hæmo rhages. I was very interested, therefore, to rea Cammidge's paper[14] on this subject. He made detailed examination of the blood in 16 cases diabetic retinitis, and the most constant finding, apa from hyperglycæmia, was calcium deficiency, 13 the cases giving figures which were distinctly path logical. The three cases with normal calcium present an ophthalmoscopic picture more in keeping wi renal than diabetic retinitis.

The calcium deficiency may arise in different way one being depletion of the alkali reserve of the bod consequent on acidosis. Another way is throug deposition of calcium in the vessel walls. Such calc fication is easily diagnosed by X rays, and is foun more commonly and in a more advanced stage i diabetics than in those not suffering from the diseas The changes found resemble those produced expe mentally in rabbits by prolonged feeding wi cholesterol, so it is thought that persistent lipæmia the determining factor.

Retinitis and cataract do not exhaust the poss bilities in diabetes; the optic nerve and the extra-ocul muscles may become affected. There is also a form iritis in which the pigment layer is very easily detach from the iris. I have seen complete optic atrop develop, but a commoner condition is a form of retr bulbar neuritis with a central scotoma, which ma clear up or go on to atrophy. A milder form of t same sort of thing is the increased sensitiveness whi many diabetics show to the toxic effect of tobacco.

BOLTON ROYAL INFIRMARY.—The King has give his assent to the title of the Bolton Infirmary being chang to the Bolton Royal Infirmary.

KING GEORGE HOSPITAL, ILFORD: NEW WARD.- A satisfactory year's working is recorded in the annu report, and the extended facilities afforded by the openi of the new buildings by the King last year have be used to the utmost. The number of in-patients resident 1931 was 97·56, each patient's stay averaging nearly thr weeks. The average cost per bed was £3 5s. 2d. A ve important feature of the year's work was the success of t contributory scheme, which, although still in its infanc looks as though it may go far towards solving the proble of maintenance.

For the second time within a few days a new ward h been opened at this hospital. It contains 27 beds, and h been provided, at a cost of £10,000, by Captain Erskin Bolst, M.P. for Blackpool. It was formally opened b Lady Hamilton, wife of Sir George Hamilton, M.P. fo Ilford.

THE ASBESTOSIS BODY

BY S. ROODHOUSE GLOYNE, M.D. LEEDS, D.P.H.
PATHOLOGIST TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK

DURING the past two or three years observations on the asbestosis body have been published with such frequency that it is very difficult to keep track of them all. In this paper I have endeavoured to bring together, as far as possible, all the work from different sources and at the same time to add such facts as have come under my personal observation.

HISTORICAL INTRODUCTION

In 1914 Fahr [1] demonstrated to the Medical Society of Hamburg specimens and photomicrographs of the lungs from a case of pneumonoconiosis occurring in an asbestos worker. He mentioned the presence in the lung of a large number of crystals and stated that similar structures had been seen in 1906 by Marchand and Riesel, who had speculated as to whether they were due to the inhalation of asbestos dust or were a hæmoglobin derivative. Unfortunately no pictures are given in the brief report of Fahr's communication and I have been unable to find any further record of Marchand and Riesel's observations, but it is probable that what both Marchand and Riesel and Fahr saw was the asbestosis body. However, these descriptions attracted little attention at the time and seem to have been forgotten.

The next indication that the fibrosis induced by asbestos revealed anything unusual came in 1927 when Cooke and Hill [2] and Stuart McDonald [3] described certain curious bodies found in the lungs of an asbestos worker who had died in 1924. Cooke [4] had previously recorded the case in 1924 but had not at that time mentioned these curious bodies. In the account published in 1927 Cooke and Hill gave the following description of them:

> "They are yellowish-brown in colour and do not stain with the usual stains, but give the Prussian blue reaction. There is a uniformity in appearance, group distribution, and fructating heads that make one think of a fungus. The hyphæ are verruciform and discoid, and definite spores are seen. Many cases are recorded of infections of aspergillus and penicillium occurring with tuberculosis."

They submitted the sections of the lungs containing these bodies to various workers. Some workers considered them to be radiolaria spicules, others diatomaceæ, others "casts of small cavities," others "particles of asbestos fibre that have become coated with colloidal matter." Others again believed these structures to be fungoid bodies and on morphological grounds suggested them to be aspergilli, penicillia, or hyphomycetes with septate hyphæ. The authors quoted in support of this last view an account given by Scott [5] of a new hyphomycete found in batrachians, *Monilia batrachia*.

Later in the same year Stuart McDonald, to whom post-mortem material had been submitted from the same case, gave a fuller description of the bodies. He described them as foreign bodies of a distinct yellowish-brown colour suggesting blood pigment, some elongated, some rounded and homogeneous, some annular and appearing to consist of a closely set series of rounded discoid bodies, others again simulating sporangia of a hyphomycete or even minute crustaceans. (Beintker [5a] has likened various forms to sea-lilies, roots, boats, and dumb-bells.) But closer examination did not support the idea that they were either vegetable or animal in origin. On this point Stuart McDonald was quite definite. He also quoted another case of an asbestos worker in whose lungs he had found similar bodies.

The first illustrations of the bodies were given by Cooke and Hill in their original description. Subsequently they were depicted by Simson [6] in autopsies of South African cases. His paper also included a microphotograph of the bodies produced experimentally in the lung of the guinea-pig by Mavrogodato, the first occasion on which the bodies had been produced experimentally. At this stage Stewart and Haddow [7] made the suggestion that the bodies should be called "asbestosis bodies," a term which has now been generally adopted.

THE MORPHOLOGY OF THE BODIES

The diversity in shape makes it almost impossible to write an adequate description which will fit all forms. The following summary comprises, however, the chief points:—

1. Marked variation in length (24–60 μ) and breadth (12–24 μ). Gardner and Cummings record them as long as 250 μ in experimental animals. The short forms are sometimes seen within phagocytes.
2. Golden yellow colour. Gardner and Cummings have pointed out the resemblance of this colour to the hæmosiderin deposits found in areas of tissue in which hæmorrhage has occurred.
3. Homogeneous structure when viewed by ordinary transmitted light.
4. By cutting down the light a suggestion of a central fibre can often be seen. This fibre may also sometimes be seen projecting beyond the body.
5. No differentiation with polarised light (Cooke and Stuart McDonald).
6. Tendency to be arranged in irregular clumps and clusters.
7. Very early forms unsegmented ("sausage shaped").
8. Later forms crenated, segmented, or resembling a series of oval discs, or beads strung together in a necklace form. Sometimes, later, a short length of fibre is seen between the segments.
9. Bulbous or pointed extremities (or one bulbous and one pointed suggesting "heads and tails"). Simson and Strachan have noted sharply angled forms suggesting incipient fracture, and believe that the tapering tail forms may be the broken ends of this fracture.
10. Generally quite straight, occasionally curved, very rarely S-shaped. When examined in a wet preparation slight pressure on the cover slip will sometimes cause them to bend owing to the elasticity of the central fibre. This liability to bend under stress and strain may explain the curved forms often seen in sections of tissue, as suggested by Gardner and Cummings.
11. Forms seen "end-on" look like knobs or door-handles. Small secondary knobs and bosses sometimes seen thereon.

METHODS OF DEMONSTRATION

1. *Sputum*.—Stewart and Haddow first found the bodies in sputum by digesting the sputum with an equal quantity of undiluted antiformin, centrifuging, washing the deposit, and examining a dried film. Or the deposit can be examined wet like a urine. Occasionally the bodies can be found in a direct film from sputum without centrifugation.

2. *Lung*.—Stewart [8] also found asbestosis bodies in direct films from lung juice at the time of the post-mortem examination; Stewart and Haddow demonstrated them in tissue juice obtained by lung puncture during life. In sections they stand out well unstained against the stained background of hæmatoxylin and eosin, but they are really best seen in an unstained section. Beintker recommends decolorising with chlorine, which enables the central fibre to be seen, but takes out much if not all of the golden yellow colour.

Fæces.—There is often no sputum in cases of pulmonary asbestosis until late in the disease. In such cases it is possible that sputum is produced but swallowed, as is not infrequently the case in pulmonary tuberculosis. On one occasion I found [9] asbestosis bodies in the fæces by emulsifying with formol-saline, centrifuging and examining the deposit. The bodies, though clearly recognisable, were scanty in number and not so deeply coloured with yellow pigment as usual, as though partial digestion had taken place.

STAINING

The bodies do not stain with the ordinary aniline dyes used in routine laboratory work, but according to Gardner and Cummings Wright's blood stain gives them "a greenish cast." They will also retain neutral red slightly, but these partial reactions cannot be called true staining reactions. Cooke and Hill and Stuart McDonald, in their original descriptions, noted that the bodies could be stained by means of the Prussian blue reaction. For ordinary purposes of identification staining is unnecessary but coloration of the bodies is sometimes helpful, particularly in sputum where they are apt to be scanty and to be obscured by cellular debris. Staining is also valuable for obtaining more detail of the outline of the subsidiary bosses of the body and for detecting the presence of the central fibre. It is also distinctly helpful in making photomicrographs. In the case of sputum I have used the following technique[10]:—

> After digestion of the sputum with equal quantities of concentrated antiformin and centrifugation, the antiformin is pipetted off, and the deposit covered with a small quantity of a 5 per cent. solution of ammonium sulphide. The asbestosis bodies are then coloured black. This colour can be removed with hydrochloric acid.

In the case of sections the following technique has been found useful:—

> After removing the paraffin wax with xylol and alcohol in the usual way, the section is washed with water and then flooded with ammonium sulphide, which is allowed to remain for several minutes. The section is next washed and counter-stained with an aqueous solution of neutral red, dehydrated, and mounted in balsam. This method of staining also shows the presence of a large amount of iron in the sections. Unfortunately the black colour is slowly removed by the mounting fluid, and the sections will only keep for a few weeks.

Hæmatoxylin, which also has an affinity for iron, can be made to colour asbestosis bodies, but it is more a deposit of stain that a true staining reaction. The technique is as follows:—

> After digestion of the sputum with equal quantities of concentrated antiformin and centrifugation, the antiformin is pipetted off and replaced by a 5 per cent. solution of Ehrlich's hæmatoxylin. Blueing of the hæmatoxylin immediately takes place owing to the remains of the alkaline antiformin. The mixture is well shaken and allowed to stand for half to one hour, and then centrifuged again and the deposit mounted as a wet preparation. By this means the asbestosis bodies become a dark brown to black colour, according to the length of time they have been exposed to the hæmatoxylin.

Although these hæmatoxylin-coloured bodies give the impression of having the hæmatoxylin deposited on them rather than having actually taken up the stain, after washing overnight they still retain sufficient stain to give a dark brown effect with transmitted light.

THE FORMATION OF THE ASBESTOSIS BODY

No asbestosis bodies have been found in crude asbestos or in asbestos dust, and it seems practically certain that they are only produced when the fibres gain access to living tissues and remain there for a considerable period of time. The asbestos fibre which forms the central core of the bodies was identified by me[11] by the following experiment:—

> A wet preparation of the bodies was placed on the stage of the dark-ground illumination microscope, and the position of a readily recognisable group of these bodies noted. Concentrated sulphuric acid was then run very gently under the cover slip, the bodies being kept under observation all the time. They began slowly to dissolve, and in the middle of the structure of each appeared a typical asbestos fibre. At the end of half an hour practically all the material of which the bodies were composed had disappeared, leaving only faint ghost-like outlines with refractile asbestos fibres within them.

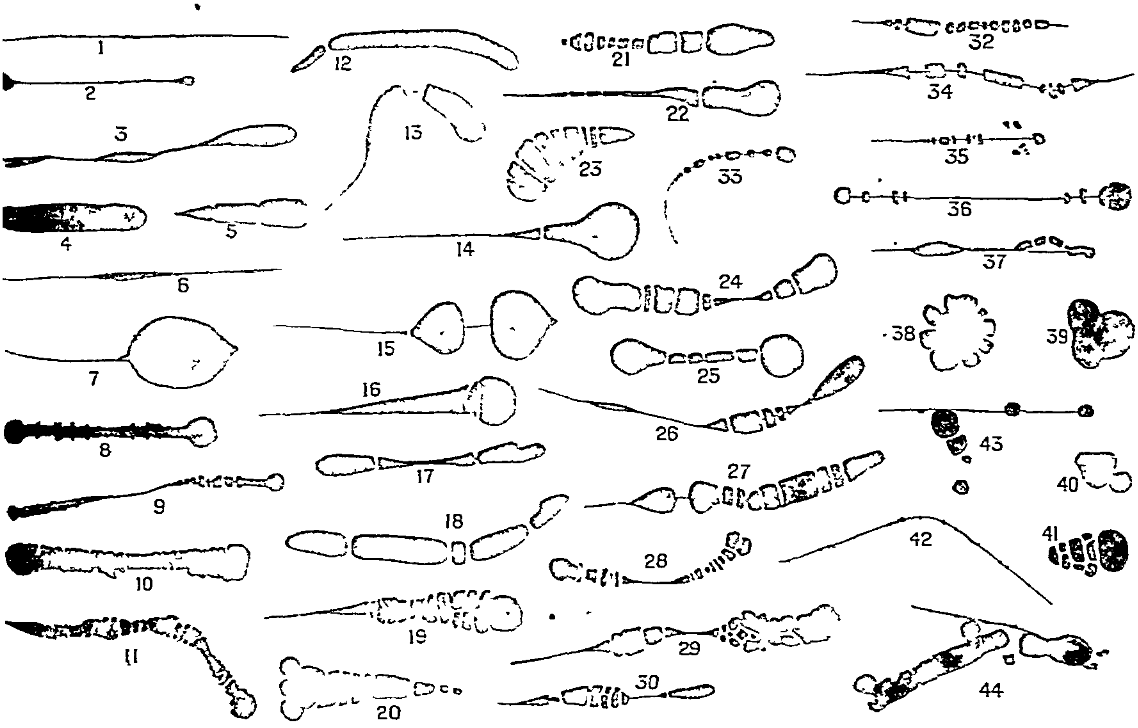
Gardner and Cummings[12] next showed that the golden yellow material which covers the fibre contained iron. Iron-free asbestos fibres were impregnated with an iron salt by heating to dryness in a dilute ferric chloride solution and igniting. The fibres were then placed in a solution of sodium silicate. The iron salt adhering to the fibres reacted rapidly with the silicate producing a curiously shaped golden-yellow structure which bore some resemblance to the asbestosis body. They further showed that in lung sections the earliest forms encountered consisted of iron containing, sheath-like or nodular swellings along the sides or at the ends of a fibre. From these points further extensions occurred until in some cases the whole filament acquired a uniform coating which was brittle and finally began to crack thus separating the body into segments. Beintker also suggests that a silicate enters into the formation of the body.

Simson and Strachan,[13] in reporting asbestosis bodies in the sputum of 50 workers in an asbestos mill in South Africa, considered from a study of the intracellular asbestosis bodies in these cases that they were formed by the deposition on the asbestos fibre of an iron-containing substance elaborated by the cell. They state that in carefully prepared direct films of sputum the bodies are always intracellular and that the fibre becomes coated with the characteristic pale greenish-yellow or golden-yellow substance which gives the Prussian blue reaction. This coating may be uniform except at the extremities where there is a bulbous enlargement. After the deposited material has increased segmentation appears, becomes deeper and finally fracture of the fibre takes place. It is, in their view, this fractured end which gives the appearance of the crustacean-like tail sometimes noted. This tail may become bulbous again. The authors believe that it is the alveolar phagocyte and not merely the body fluid which is the source of the material which goes to form the asbestosis body.

From a study of a large number of different forms of asbestosis bodies, I have endeavoured to build up a complete picture of formation from the original inhaled fibre.[14] Figs. 1 to 3 show deposition of some material on the fibres to a varying extent. When completely covered the body thus formed has a sausage-like form without any differentiation from end to end (Fig. 4). These thickened forms next begin to show definite fissures (Figs. 5 to 7) giving the appearance of incomplete segmentation at irregular intervals. In Fig. 8 this segmentation has advanced a stage further, the fissures now extending almost to the middle line of the body at irregular intervals along its length. These fissures also give the appearance of a head at the ends (Figs. 9 and 10). As they become deeper and more numerous a completely but irregularly segmented body results (Fig. 11). When the fissures reach the straight central fibre they appear as (*a*) a small number of long segment as in Figs. 12 to 18, or (*b*) a large number of short segments as in Figs. 19 to 34. These short segments may be regular in size and shape resembling beads on a necklace (Figs. 32 to 34) or the segmentation may be complete at one end of the body and incomplete at the other.

In this final stage some of the segments break away (or even small portions of segments), leaving bare lengths of fibre between the remaining segments (Figs. 35 to 37). Very occasionally these broken gments can be actually seen in the process of eaking away. This is well shown in Figs. 35 and 37. dies viewed end-on or obliquely are seen in Figs. 38 41.

The asbestosis body would appear, therefore, to formed from the original fibre by a process of) deposition of some material around the fibre as to thicken it; (2) fissure or cracking of this terial giving rise to the appearance of segments; d (3) fragmentation or the separating off from the bestosis body of fractured portions of the deposited terial. Timmermans[15] has recently suggested that e shape of the asbestosis body is conditioned to a rge extent by the surrounding tissue, handle-shaped rms being produced in places where there is no ovement, and carrot-like forms where the tissue id is in motion. This explanation would seem to ve less force when the asbestosis bodies are oduced experimentally in subcutaneous tissue.



Various forms of asbestosis body.

THE COMPOSITION OF THE BODIES

Of the various original speculations as to the mposition of these bodies that of asbestos fibres ated with colloidal matter has been most nearly rrect. The central fibre having been demonstrated o questions have to be answered. What does this lden yellow material consist of? Where does it me from? Cooke at one stage suggested that some the coccal and spore forms of the bodies might formed by bacterial action. Subsequently, how-er, in collaboration with Hill,[16] he came to the nclusion that the asbestos fibre became enveloped minute extravasations of whole blood or serous udate. When these workers submitted the bodies film preparations to X ray examination with the agg technique they came to the conclusion that e "greater proportion of the composition of these dies was of non-mineral origin." Gardner and ummings also failed to obtain X ray shadows with the Bragg technique, but did not draw the same conclusion. Schuster[17] concludes that asbestosis bodies may be found with or without inflammation, that there is no causal relationship between the two phenomena, and that whatever juices take part in the construction of the bodies they are produced during normal metabolism. Simson and Strachan incline to the view that the coating of the fibre is derived from the phagocyte.

The early observations of Stuart McDonald had shown that the asbestosis body took on the blue colouration of the Prussian blue reaction, thereby indicating that iron entered into its composition. The work of Gardner and Cummings, of Simson and Strachan, and the present writer, referred to above, confirmed this fact. There is evidence, however, that iron is probably not the sole constituent of the golden-yellow coating material. With regard to the second question, the source of this iron fraction of the body may conceivably be either the asbestos itself or the body tissues. Three varieties of asbestos are used in industrial processes (Merewether[18])—chrysotile, crocidolite, and amosite. The first named, which forms the largest part of the supply at the present time, contains 0·7 to 4·4 per cent. iron. Crocidolite and amosite, limited to the use of certain factories connected with the South African trade, contain 35·5 to 37·4 per cent. and 34 to 44 per cent. respectively. This iron probably chiefly occurs in the form of silicate of iron. As far as we know all asbestosis bodies, whatever the origin of the causative asbestos, give an iron reaction. With regard to the tissue origin, iron in body tissues is chiefly derived from oxyhæmoglobin, though there are also minute traces of it in protoplasm. The amount of iron in oxyhæmoglobin is practically constant (Starling[19])—viz., 0·336 per cent.

With a view to the determination of this question Gardner and Cummings prepared a mixture of equal parts of very finely divided asbestos fibre and fine whole asbestos dust, divided the mixture into two parts, removed the iron from one part by digestion with hydrochloric acid, keeping the other part as a control, and injected saline suspensions of each part subcutaneously into guinea-pigs. The iron-free suspension was injected into the left groin of the animal and the control into the right. At the end of 60 days animals showed fibres but no bodies on the right side, but no injected material at all on the left. The equivocal results of this experiment was, as the authors suggest, probably due to lack of sufficient time allowed for the development of the asbestosis bodies.

Meanwhile, unaware of the above experiment, I had carried out a test on similar lines with a more successful result. It had previously been shown[20] that in spite of the high resisting powers of asbestos a certain loss of weight occurs with strong acids. A small portion of blue asbestos was therefore boiled in pure concentrated hydrochloric acid with repeated changes of acid until the final acid gave no iron reaction with potassium ferrocyanide. The asbestos was then suspended in sterile water rendered slightly alkaline and injected into the inguinal region of six guinea-pigs. The amount of asbestos used was very small, and in four of the animals it could not be discovered at autopsy. In one animal, however, killed nine months after injection, a small nodule containing asbestos was found in the thigh muscles. On histological examination of this nodule, which consisted chiefly of connective tissue, a number of small but quite typical asbestosis bodies were found. These bodies gave an iron reaction with ammonium sulphide and with the Prussian blue test. This experiment suggests that the iron of the asbestosis body is derived from the body tissues.

EFFECT OF FERMENTS ON ASBESTOSIS BODIES

As mentioned above, asbestosis bodies found in the fæces in a case of pulmonary asbestosis showed some evidence of digestion. The following experiments were performed to test the effects of other ferments :—

Artificial gastric juice.—Sputum containing asbestosis bodies was digested for 24 hours with an equal quantity of artificial gastric juice with and without previous treatment with antiformin. The centrifuged deposit showed typical asbestosis bodies, but in each case the pigment in them appeared to be slightly less. They gave an iron reaction, however.

Trypsin.—Cooke and Hill record that the bodies resist the digestive action of trypsin when portions of lung are placed in this material. I found that when sputum was digested with trypsin for one week the bodies were destroyed, but in lung tissue some survived.

Autolysis.—Sputum containing asbestosis bodies was allowed to remain in the incubator and autolyse for 14 days. At the end of the first week asbestosis bodies were still present ; by the end of the fortnight only a few very imperfect bodies were found though many asbestos fibres were seen.

Caseation.—In a group of 12 guinea-pigs infected with a feebly virulent strain of *B. tuberculosis* after two years' exposure to asbestos dust, Gardner and Cummings noted that the development of caseation in an area containing asbestosis bodies led ultimately to the destruction of the bodies. They lost their characteristic golden-yellow colour, failed to give a Prussian blue reaction, and were apparently so completely disintegrated that not even a supporting fibre remained. Polarised light also failed to reveal refractile elements. The authors make the suggestion that the change in hydrogen-ion concentration incident to caseation may favour solution of the foreign bodies.

In the lungs of human cases Wood and Gloyne[21] found asbestos fibres and asbestosis bodies lying side by side in caseous areas, but it was impossible to determine whether the fibres were the remains of dissolved asbestosis bodies. The bodies still gave iron reactions.

According to Wells, De Witt, and Long[22] two ferments probably play a part in the caseation of tuberculosis : (1) an autolytic enzyme causing cell coagulation, &c., in the early stages ; and (2) a proteolytic ferment which is responsible for the subsequent breaking down, and is induced by secondary infection and leucocytic invasion. If the caseation were to take place in an area of tissue already stocked with asbestosis bodies the autolytic ferment might conceivably have some destructive effect on the asbestosis body. Again, if asbestosis bodies were to enter an area already caseous—an unlikely contingency, since asbestosis bodies have little power to migrate—they might conceivably act as a secondary infection and induce proteolytic action resulting in their destruction. Whether the so-called autolytic ferment of caseation or the proteolytic ferment o secondary infection be responsible, the result is probably, at the long last, the same—viz., destruction of the asbestosis body.

EFFECT OF HEAT ON ASBESTOSIS BODIES

In one experiment asbestosis bodies resisted boiling for two hours, whilst the water showed no trace o iron. In another asbestosis bodies resisted boiling for four hours. Timmermans also found that they resisted dry heat.

EFFECT OF ACIDS AND ALKALIS

The effect of acids on the asbestosis bodies varies a good deal. In sections I found that they resisted decalcifying fluid which contained 7½ per cent. o nitric acid, for several weeks. Concentrated sulphuric acid leaves only a mere semblance of a *ghost-like* body with a central fibre. Generally this dissolving action takes place within a few minutes, but it may be delayed for several hours. It is possible that thi is due to some of the bodies being large, harder, and more resistant than others, but it seems more likely that inasmuch as the bodies are always examined in an impure medium such as sputum or lung tissue or fluid, some mechanical factor prevents the sulphuric acid reaching quickly certain individual bodies Hydrochloric acid has the effect of bleaching the bodies ; the yellow colour is taken out almos immediately leaving a colourless skeleton of the body, suggestive of a minute hyaline urinary cast Sometimes the body becomes swollen and the segmentation is lost ; at others the segments seem to remain intact. The effect of hydrochloric acid is interesting in that the golden-yellow colour is discharged but the ghost-like structure of the body remains. The inference here would appear to be that the body consists of at least two portions surrounding the fibre—viz., a resistant materia which forms a framework and gives the body the characteristic shape, and a golden-yellow pigment which is readily bleached. Nitric acid has less effect ; the yellow colour is only to a small extent discharged and even when the bodies are left exposed to the acid for 24 hours in the cold they still retain a light yellow colour and the segments are intact. Glacial acetic acid appears to have no effect.

Cooke states that the bodies are soluble in strong kalis. I have noted, however, that they remain tact with practically no discharge of the golden-llow colour when left in 20 per cent. caustic soda r 24 hours.

ATTEMPTS TO PRODUCE THE BODIES IN VITRO

Attempts were made to produce asbestosis bodies vitro by exposing sterilised ground-up asbestos res for a whole year both at room and at body nperature to the following substances in the hope at the fibres might be made to swell up or take on a posit which would simulate the asbestosis body: concentrated sulphuric acid; (2) concentrated ric acid; (3) ferric chloride; (4) sodium silicate; trypsin; (6) bile; (7) calcium lactate (1 per cent. ution); (8) saturated calcium chloride; (9) 1/1000 loidal calcium—whole blood and blood-serum re also tried for rather shorter periods. The ric acid specimens showed a tendency to oblique mentation, corkscrew and granular forms such as seen in asbestos which has been boiled with ong hydrochloric acid. In the three calcium eparations, both at room and body temperature, the res showed a definite feathery thickening, presum-ly from a deposit of calcium salts on them, but ere was no real resemblance to asbestosis bodies. effects were noted in any of the other substances.

Gardner and Cummings have succeeded in preparing dies superficially resembling asbestosis bodies by following method: iron free asbestos fibres were pregnated with an iron salt by heating to dryness a dilute ferric chloride solution and igniting. e fibres were then placed in sodium silicate solution. e iron salt adhering to the fibres reacted rapidly h the silicate, producing a curiously shaped den-yellow structure which resembled the asbestosis dy.

WHAT INFERENCE CAN BE DRAWN FROM THE PRESENCE OF THE ASBESTOSIS BODY?

From the presence of the asbestosis body in the tum certain deductions can be made.

(1) Since these typical bodies have not been found any other disease, their presence is an indication of posure to asbestos dust.

(2) The fact that the bodies have not been found asbestos dust implies that their formation is the ult of some tissue reaction in the body—probably colloidal reaction in which the iron plays a part.

(3) Asbestosis bodies have been found in the guinea- by Mavrogordato four months after exposure, Stewart three to five months after exposure, Gardner and Cummings 70 days after exposure, d by the present writer six months after. Simson recorded the bodies in a human lung with a tory of only two months' exposure. The human ng does not of course constitute quite such a clear- test, since the exposures are not so carefully trolled. It may be assumed, however, that the sence of asbestosis bodies in the sputum means at asbestos fibres have been present in the lung for ny weeks at least.

(4) Lastly, can it be deduced from the presence of asbestosis body in the sputum that fibrosis cessarily exists in the lung? Simson and Strachan ve already answered this question in the negative. e presence of the asbestosis body implies a tissue ction to the fibre, but it does not necessarily follow at this reaction is accompanied by fibrosis. On one casion I found fine connective tissue fibres in sections a guinea-pig as early as 12 days after subcutaneous inoculation of asbestos fibres, but the amount was very minute. A heavy dose of fibres would be needed —and even then years might elapse—before the fibrosis was sufficient to be detected by physical signs or radiogram or to produce dyspnœa. It would be unsafe, therefore, to accept the presence of the asbestosis body as undeniable evidence of fibrosis; all we can say at present is that the asbestosis body is an expression of tissue reaction of the nature of a benign irritant, and that fibrosis of an appreciable extent may or may not be a part of that tissue reaction.

PRODUCTION OF THE ASBESTOSIS BODY IN ANIMALS

As stated above the production of the asbestosis body in the lungs of the guinea-pig was achieved by Mavrogordato and others quite early in the research. Gardner and Cummings noted that the bodies were less easily produced in the subcutaneous tissues of the animal. (In passing it may be noted as a fact of possible significance that the bodies have not yet been described in the skin warts to which the workers are liable. I have examined without success sections of a wart which was known to have been present for many weeks, and have failed also to find them in the skin of a guinea-pig seven months after the asbestos fibres had been introduced into the cutaneous tissues. Dewirtz[23] also does not make any mention of asbestosis bodies in sections of warts in Moscow factory workers.)

Gardner and Cummings also record that the lung of the rabbit apparently offers a much less favourable environment for the production of the bodies than does the lung of man and of the guinea-pig. Nothing faintly resembling the asbestosis body was found, they state, in the rabbit until the dust exposure had been continued for a period of 11 months. These authors furthermore found the white rat very refractory. Only two asbestosis bodies were found, though they consider that their negative result may have to some extent been vitiated by the widespread incidence of natural chronic pulmonary infections in their animals. After careful search I found only one small but typical body in the lung of a grey rat caught on an asbestos factory premises, though there were large numbers of fibres present. The length of exposure, however, cannot in this case be verified.

Schuster examined the lungs of a rough-haired terrier which had been kept on factory premises for the purpose of ratting. The animal was 10 years' old and had been living in the factory nearly all his life, with access to all parts of the building. He had suffered for two years from cough and dyspnœa and for six months from progressive wasting. No trace of asbestosis bodies was found in several sections and staining for the Prussian blue reaction gave no additional information, although the histology of the lung was typical.

Obviously much work is needed before this side of the problem can be elucidated, but it seems clear that not all animals will produce the asbestosis body with equal facility.

I am indebted to Miss P. E. Double for the drawings of the asbestosis bodies.

RESULTS OF THE SO-CALLED
TONSILS AND ADENOIDS OPERATION

By James Kerr Love, M.D., LL.D.,
F.R.F.P.S. Glasg.
HON. AURAL SURGEON TO THE GLASGOW ROYAL INFIRMARY

Some months ago I stated at the Otological Section of the Royal Society of Medicine that at the present rate of operating a fourth of our population were, during the school period, being deprived of tonsils and post-nasal adenoids.

I was surprised myself at the above statement and would fain have found myself mistaken, but as I found that 6000 out of a yearly admission of 22,000 children were being operated on at various centres in Glasgow, there was no escape from the conclusion. I was forced to ask myself if this operation was necessary; did the ends attained justify the disturbance to the child and the cost to the community? In other words, what are the end-results of the so-called T. and A. operation? The thesis of this short paper is that the results justify the disturbance to the child and the cost to the community. But I contend that many of us remove tonsils too often or too soon and that we do not remove post-nasal adenoids often enough or early enough. I contend that we have become slaves to a phrase, that we should speak of T. and A. operations but separate them in thinking and in practice and speak of the operation on the tonsils and that on the post-nasal adenoids. Of course they belong to the same anatomical ring but that ring does not become diseased round its whole circuit or arc in every case. Even when the whole ring becomes involved, the adenoids infection usually precedes that of the tonsils, though sometimes of course the order of invasion may be reversed.

My conclusions are based on the work done during the last 15 years at the instance of two education authorities, that of Glasgow and that of the county of Dunbarton, representative on the one hand of typical city life and on the other of mainly country life. Dr. Napier Grant is my colleague in the city work. I am the only operator for the county authority. About 23,000 operations have been done —12,000 in the city and 11,000 in the county. No death has occurred from bleeding either primary or secondary and none under an anæsthetic where t T. and A. operation alone was done. It is clear impossible to associate all these cases—in spite of t fact that careful records exist in every case—with recent or present-day examination or inspection. B the school records are the best in the country in o respect at least, for they cover nine or ten years of t life of the school child.

AN INQUIRY IN GLASGOW

Two methods of approach appealed to me:—

1. The statistical which I applied to recent Glasgow cas operated on during the past eight years.

2. Opinions derived from the observation of the medic men who see our patients for years before we operate a have to treat them for years after we lose sight of the And the general practitioners form the high court of judgme in a matter of this kind.

This second method I have used in the county cases

I was lucky to find that Dr. Arbuckle Brown, no chief medical officer of the Glasgow authority ha during the years 1924–25 examined 213 children, the average about six to nine months after operati and had tabulated the results. With the help of m assistant, Dr. Ian Thorburn, I undertook to exami a new batch who had been operated on 12 to 18 mont previously. This lot amounted to 280, so that we h carefully prepared end-results from a series of nea 500 cases. As the parent was in almost every ca present with the child when the examination of t child was made, a fairly correct and full account the results of operation was got.

In these Glasgow cases records were taken under t following headings: (1) throat and chest conditions i.e., sore-throats, recurring colds, bronchitis, hoar ness, &c.; (2) mouth-breathing or nasal obstructio (3) adenitis; (4) hearing—slight or marked deafne (5) aural discharge; (6) nasal discharge. The eff on the general health was also noted as reported by t parents.

I shall call Dr. Brown's cases Group I. and my o Group II. The general health figures in Group (280 cases) are as follows: 49 were much improv 193 were improved, and of the remaining 38 cases (change) 5 had good health before the operation. did not expect the operation to do everything—e. to cause the cessation of aural discharge in an case of scarlet fever, or to cure the Glasgow acce which is not one of the best in the country.

Comparing Dr. Brown's list (Group I.) with my o list (Group II.)—

Out of 280 cases all the symptoms disappeared	in 166 (59·3 %). (Dr. Brown, 84·0 %).
Out of 38 cases of chronic ear discharge cure resulted ..	in 22 (57·9 %). (Dr. Brown, 64·7 %
Out of 187 cases of mouth-breathing cure resulted	in 143 (76·5 %). (Dr. Brown, 93·2 %)
Out of 40 cases of deafness ..	23 were cured (57·5 % (Dr. Brown, 83·6 %).
Out of 53 cases of nasal discharge	29 were cured (54·7 % (Group II.).
Out of 161 throat and chest conditions—i.e., sore-throat, cough, &c.—assumed to be due to T. and A. disease	141 were cured (87·6
Out of 37 cases with enlarged glands	22 were cured (60 %).

My percentages in the above classes do not repres the total benefit to the child—e.g., some discha from the nose may remain although the deafness the mouth-breathing, the sore-throats, and the dam to the general health have disappeared.

Additional queries under Group II. brought out the llowing facts :—

Liability to exanthemata.—As a result of this operation it ould seem that children are rather less liable to those fections diseases where tonsillitis is usually found—e.g., arlet fever.

Liability to acute ear attacks.—An attack of acute ear ppuration occasionally follows the operation within e to two weeks. Otherwise the incidence of such attacks pears to be much lessened. One form of ear disease hich is almost always cured by the adenoids operation is *e recurring attacks of acute middle-ear discharge in young* ildren.

he chief divergence between Dr. Brown's figures and y own is that I found a larger number of scraps of nsils which had either been left or had returned. ch were nearly always towards the lower pole and ere probably due to mounding up of the lingual nsil. Out of 37 such cases only three had ever caused y symptoms. It seems likely that such imperfect perations—artistically imperfect—are too much amed. This is not an argument for tonsillotomy as gainst tonsillectomy; I favour the latter every time. ut if complete removal is essential how was it that 5–30 years ago we were able to say that tonsillotomy s perhaps the operation which in the whole of rgery was followed most commonly by good results?

QUESTIONNAIRE TO PRACTITIONERS.

In connexion with the county cases questions milar to the above were used. but this time were ddressed to the medical practitioners of the County f Dunbarton.

A. What do you consider to be the effect of the tonsil d adenoid operation: (1) on general health of the child; 2) on the local conditions in the throat, nose. and chest; 3) on hearing; (4) on the arrest of middle-ear discharge: 5) on the removal of mouth-breathing; (6) on the arrest of largement in. or the disappearance of, enlarged lymphatic ands; (7) on nasal discharge?

B. Do you know of any untoward results which follow e operation? (1) Are the children operated on more or s subject to infectious diseases than other children? 2) Do they have more or less liability to acute ear attacks an children on whom operation has not been performed?

Over 20 practitioners have made returns to the uestionnaire, and the answers may be summarised s follows :—

1. General health: nearly always good.
2. Effect on conditions in throat, nose. and chest: good.
3. Effect on hearing: good. especially if operation be ne early.
4. Aural discharge: usually good but often negative.
5. Mouth-breathing: nearly always good, especially if eration be done early.
6. Effect on enlarged glands in neck: nearly always od.
7. Nasal discharge: result often good but fails in many ses to give immediate results though later improvement ften takes place.
8. Infectious diseases after operation: less after operation. Not a single opinion to the contrary.)
9. Subsequent acute ear affections: the majority say ss liable, a few are in doubt. Only one opinion to the ontrary.

And these opinions are not given after six months or year of observation but on observations spread over everal years before and after the operation.

CONCLUSIONS AND COMMENTS

Such are the general conclusions voiced by those medical practitioners. But detailed remarks are orth quoting—e.g..

1. Adenoids should be removed early and the best results re attained in the removal of mouth-breathing. if the eration be followed by training out of the acquired habit.
2. Tonsils may often be left unless actually septic.
3. Middle-ear discharge due to other causes—e.g.. scarlet ver and measles—is not removed by the operation on the nsils or the post-nasal adenoids.
4. Nasal discharge is not always cured by *these operations*, but even in cases of apparent failure great improvement takes place in time. In this connexion it is well to remember that neither nasal discharge nor mouth-breathing will be fully relieved if there be a badly deflected nasal septum or greatly enlarged turbinals.

These conclusions suggest to me this thought, with which this paper began. We talk of the T. and A. operation: are we not the slaves of a phrase? Are we not dealing with two operations which are too often *performed together? Should they not often be dissociated?* The adenoids infection usually takes place earlier and the tonsils may escape altogether. Occasionally the tonsils suffer first and very occasionally alone. I therefore plead for the removal of adenoids as soon as nasal obstruction occurs and leaving the tonsils unless they are evidently diseased. Where there is no history of sore-throat and no enlarged glands I tend to leave the tonsils. I find this view of these cases results in my leaving the tonsils in 10–15 per cent. of the cases sent up for operation.

An argument in favour of this conservative practice *is that the removal of adenoids is followed by little* pain, whilst tonsillectomy is followed by a very sore-throat for two or three days.

Should the time come when we will be able to say in each case when a tonsil has ceased to be defensive and has become offensive a great help would accrue to the operator. In the meantime, with the diagnostic means at our command the highest skill is shown by the man who knows when not to operate.

One last remark. Does such work as we are doing represent the ultimate management of these cases? In my opinion certainly not. No one deplores more than I do the need for so many operations on young *children. In the fashion of the day one would look* towards dieting or vitamins for the solution. What the outlook will be 10 or 20 years hence I cannot say. In the meantime. let us do the best for the individual child as he comes before us.

REDUCTION OF FRACTURES UNDER LOCAL ANÆSTHESIA

BY E. L. BARTLEMAN, M.B. EDIN.
CASUALTY AND OUT-PATIENT OFFICER, WEST LONDON HOSPITAL
AND
G. O. TIPPETT, M.B. LOND., F.R.C.S. ENG.
LATE CASUALTY AND OUT-PATIENT OFFICER AT THE HOSPITAL

MUCH experimental work has already been done abroad on the reduction of fractures under local anæsthesia. The earliest mention of the method is in 1885 by Conway.[1] During the early part of this century occasional references are found. but the advantages to be gained by it have not been put forward to any extent in the medical press. Since the war the method has again come to the fore; in Vienna, Prof. Böhler has used it with great success as a routine, as he describes in his masterly little book.[2] In 1931 Hosford[3] recorded a series of cases of fractures reduced under local anæsthesia at St. Bartholomew's Hospital. As far as we can ascertain. however, the method has not been tried out in any of the out-patient departments of the teaching hospitals, and any work that may have been done has been of an experimental rather than of a routine nature.

---

[1] Conway, J. R.: New York Med. Jour., 1885, xlii., 632.
[2] Böhler, Lorenz: Treatment of Fractures, Vienna, 1929.
[3] Hosford, J. P.: Brit. Jour. Surg., 1931, xviii., 546.

During the last 12 months we have reduced under local anæsthesia *all* the simple fractures that have come through our hands in the casualty and out-patient departments at the West London Hospital, and we set forth our views of this method after trying it on some 116 cases in the routine work of the departments.

The advantages of the method are as follows:—

(1) The immediate relief of pain and discomfort.

(2) A general anæsthetic, with its risks and unpleasantness *to the patient, is avoided.*

(3) Its applicability in the case of the aged, the shocked, and other patients for whom a general anæsthetic is undesirable.

(4) If further reduction has to be carried out at a later date, the patient is less likely to object to manipulation under a local than under a general anæsthetic (Böhler).

(5) The reduction can be performed single-handed; hence its special applicability to general practice.

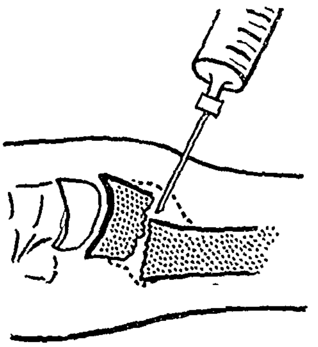
(6) The method can be safely used in the X ray room should the surgeon require to perform the manipulation under the fluorescent screen.

TECHNIQUE

The apparatus we employ is of the simplest, consisting of one 10 c.cm. record syringe, one hypodermic needle (No. 17), and one large-bore exploring needle (B.W.G. No. 18); the novocain can be carried in tablet form and made up to a 2 per cent. solution.

The site of fracture having been determined, either clinically or by X rays (the latter being especially useful but not essential), the skin over the area is cleaned and painted with iodine and then anæsthetised with a 2 per cent. solution of novocain, using the hypodermic needle. The exploring needle is then introduced obliquely through the anæsthetised skin down to the fractured bone ends (Fig. 1). Throughout this procedure the piston of the syringe should be gently pressed so that the point of the needle follows a flow of the anæsthetic solution.

FIG. 1



Anæsthetisation of the periosteum.

The operator must now satisfy himself in the following way that the needle is between the broken *bone ends:*—

(*a*) He can feel the fractured ends of the bone with the point of the needle.

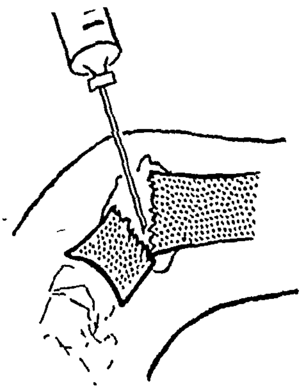
(*b*) *If the piston of the syringe is withdrawn blood will* flow into the syringe, showing that the point of the needle is in the hæmatoma present at the site of all fractures. (This of course applies to recent fractures, before the hæmatoma has had time to organise.)

Then 20 c.cm. of the solution is introduced and the needle withdrawn. After waiting three minutes disimpaction is commenced (Fig. 2). It may or may not be necessary to make subsequent injections from different angles. After five minutes the part will be completely anæsthetised, and complete and painless reduction can be carried out. That anæsthetisation of the part is complete must be pointed out to the patient by movement of the fractured surfaces—a manœuvre previously painful. His entire confidence is thus gained, and this eliminates the possibility of any voluntary muscle spasm and secures complete relaxation of the part, which is essential for the subsequent procedure of correct reduction.

In a fracture about a joint, the attainment of correct anatomical replacement can be tested by active range of movement of the joint, a unique advantage of this method over the passive movements of an anæsthetised patient.

We have used amounts of 20 to 40 c.cm. of 2 per cent. novocain for the average fracture of the *smaller bones* (Colles's), though one of us used 100 c.cm. for the operation of disimpacting a fracture of the neck of a femur in a man aged 46.

FIG. 2



The periosteum has been anæsthetised and disimpaction is now possible.

RESULTS

The following list shows the types of fractures in which we have employed local anæsthesia.

	Number reduced
Fractures of the Long Bones	
Femur, neck of. In a male aged 46 years—a comminuted fracture of base of neck. Disimpacted and position corrected two days after injury	1
Humerus, lower third and shaft	3
Radius and ulna, all types of (especially Colles')	54
Tibia and fibula, shaft, malleolar and Pott's	10
Fractures of the Short Bones	
Nasal	3
Clavicles; before reduction or application of braces	7
Phalanges	9
Metacarpals. Comminuted (especially Bennett's) before application of plaster	5
Tarsals	2
Cuneiform } before manipulation and the application of plaster splints	2
Scaphoid } before manipulation and the application of plaster splints	3
Dislocations	
Elbow	3
Patella	2
Ankle	4
Interphalangeal	8

Also for the application of plasters over the above fractures and torn ligaments.

We have so far had no complications in this work—e.g., sepsis, injury to nerves and vessels.

The objection has been raised that the introduction of the needle is not without dangers, since it may turn the category of a fracture from simple to compound; although this may be so in theory, in practice we have had no ill-effects. Further, we have discovered no pathological changes, either immediate or delayed, from the introduction of the solution into any joint when the fracture involved the bones about one. We have also gone into the question of the effects of the novocain on the bone union, and we have found that union takes place in the normal time, as tested clinically and by X rays taken over the period of union and up to six months subsequently.

The question whether this type of anæsthetic should be used for the reduction of compound fractures is debatable; certainly, unless the solution is sterilised and isotonic, one hesitates to introduce chemical substances into an area where septic organisms are present, unless that substance be an antiseptic. Again, waterlogging the tissues might be considered inadvisable when those tissues are going to be called upon to fight sepsis. Thus we feel that in these cases it would be preferable to carry out a nerve block higher up away from the septic field.

DISADVANTAGES OF THE METHOD

(1) *Children.*—The method is not suitable for young children. The youngest child we have successfully treated was 10 years of age.

(2) *Œdema.*—In some cases, especially where the fracture is in the neighbourhood of a joint, there is much swelling, which is increased by the introduction of the novocain solution. To some extent this difficulty may be overcome by elevation of the limb, massage, and the application of an Esmarch's bandage for a few minutes.

Clinical and Laboratory Notes

CONGENITAL ABNORMALITY OF THE EXTERNAL SEMILUNAR CARTILAGE

By V. H. Ellis, B.Chir Camb., F.R.C S. Eng.
ORTHOPÆDIC SURGEON TO ST. MARY'S HOSPITAL, LONDON;
ASSISTANT SURGEON TO THE ROYAL NATIONAL
ORTHOPÆDIC HOSPITAL

Gross abnormalities of the semilunar cartilages are rare in otherwise normally developed knee-joints, though minor variations in their attachments are not uncommon. A flattened disc instead of a meniscus is the abnormality of the external cartilage which has been met with by many surgeons on rare occasions but the literature is scanty. Poirier[1] has described two cases. Timbrell Fisher[2] has recorded a case of which he gives an illustration.

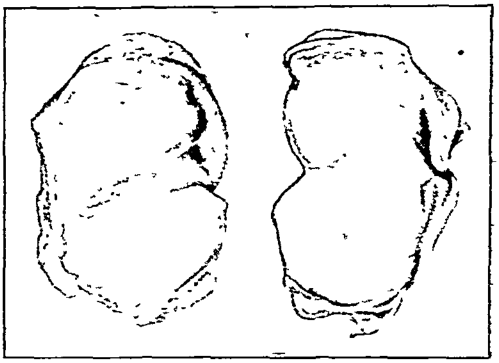
The external semilunar cartilage is developed from the mesenchyme separating the two primitive joint cavities of the knee. In many animals the external cartilage forms a more nearly complete septum than is found in man. In the apes it is in the form of a ring, a condition which occasionally occurs in man as a variation. No animal higher in the scale than the lizard is provided with a complete disc

The condition is one of surgical interest because it gives rise eventually to characteristic signs and symptoms of internal derangement of the knee-joint. It may be unilateral or bilateral. In both cases described below the patients were girls whose symptoms commenced during childhood.

The usual history is that on straightening the knee from a flexed position there is an audible and palpable thud. After months or years the knee becomes painful and occasionally there is effusion into the joint. On examination the joint appears to be normal and there is no local tenderness. Flexion and extension are both free and full but on extending the knee, at a point where the leg makes an angle of about 170° with the thigh, there is a loud thud. the tibia rotates slightly on the femur, and the anterior part of the external cartilage becomes palpable to the outer side of the patellar tendon.

This movement within this joint has not as a rule the same character as the click heard on examining a torn or abnormally mobile external cartilage of normal type but gives the impression that there is some larger obstacle jammed between the condyle of the femur and the tibia. Differential diagnosis is also made easier by the fact that derangement of the external cartilage is uncommon in children and is usually preceded by a definite injury. Removal completely relieves all symptoms.

The accompanying illustration shows the left and right external cartilages. The upper surface shows the depressed area on which the condyles of the femur rotate. On the postero-lateral edges the grooves for the tendon of popliteus are clearly visible. Each cartilage is extremely wide and formed an almost complete septum across the outer half of the knee-joint. The medial free border was not longer than 5 mm.



Drawing of the external cartilages from Case 1.

Case 1.—Girl aged 13. Complaint of the knees "giving way" for six or seven years. No history of injury. The knees also click and are painful at times. She gave a vague history of locking of the joints and effusion into them. On examination no effusion or tenderness of the joints which have a full range of movement. In the right knee there is a definite bump on the outer side felt on extending the knee at 170°. The condition of the left knee is similar but not so pronounced.

Both external cartilages were removed by operation. The cartilages (see Figure) were extremely wide, forming an almost complete disc across the outer half of the knee-joint. The inner free borders were not more than 5 mm. long. Each cartilage showed a depressed area on which the condyle of the femur rotated.

Case 2.—Woman aged 26. When aged 10 the left knee became suddenly locked in flexion and it was straightened by her doctor. Since then it has always clicked painfully on extension. On examination the knee was not swollen or tender. On extension there was a painful bump which could be felt over the outer side of the joint.

The external cartilage was removed by operation. It formed a complete section across the outer half of the joint and appeared to be wedged at times between the joint surfaces.

I am indebted to Mr. E. P. Brockman for permission to publish these cases.

A CASE OF NODAL RHYTHM

By F. Bennett Julian, M.C., M.B., M.Sc. N.U.I.
HON. PHYSICIAN TO THE LIVERPOOL HAHNEMANN HOSPITAL

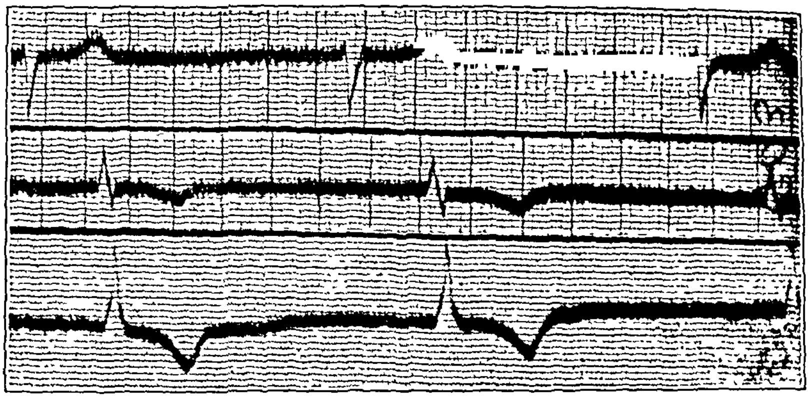
Nodal rhythm was a term originally used by Sir James Mackenzie to describe that condition which Sir Thomas Lewis in 1910 showed to be due to fibrillation of the auricle. Mackenzie evidently thought that, the auricle being completely paralysed, as evidenced by the absence of the auricular wave in jugular and liver tracings, the cardiac impulse was generated from the auriculo-ventricular node, or, at any rate, that the auricles and ventricles contracted

---

[1] Poirier, P., and Charpy, A.: Traité d'anatomie humaine, Paris, 1911, vol. i., p. 82.

[2] Fisher, A. G. Timbrell: Internal Derangements of the Knee-joint, London, 1924, p. 14.

FIG. 1



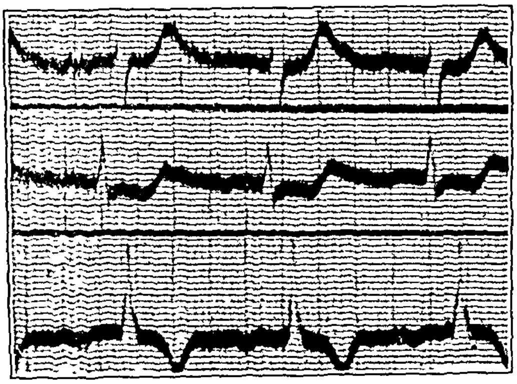
Nodal rhythm. The irregularity and absence of the P wave are noticeable.

simultaneously. Later work showed that the origin of the cardiac impulse was still the auricle, but that the auricle did not as a whole contract.

There are cases, however, in which the cardiac impulse does originate in the junctional tissues, and in which the auricle and ventricle do contract simultaneously. To these cases the term nodal rhythm is now applied. The condition is identified in the electrocardiogram by the entire absence, or in some cases by the inversion of, the P wave. The condition is not necessarily of serious clinical significance.

It is the constant rule in these cases to find that the heart action is quite regular, and so far as can be determined there have been no cases published of departures from this rule. The following case is therefore of interest, exhibiting as it does irregular nodal rhythm.

FIG. 2



Ten minutes after the administration of adrenaline 0·5 c.cm. The rate is now regular, and accelerated, and the P wave is in its normal position. It is inverted in lead II.

The patient, a girl aged 7 years, was observed to have a very slow pulse, seldom rising above 50, even when suffering from a febrile state, e.g., measles, with a temperature of 103° F. or over. She seemed healthy and happy, had a moderate appetite, and slept well. She suffered very little, if at all, from respiratory distress on exertion. Her mother stated that she was perhaps unduly tired after walking. There was no history of rheumatic or scarlet fever.

She was admitted to the Liverpool Heart Hospital for observation and was electrocardiographed on numerous occasions. Every electrocardiogram showed the same features—viz., a slow irregular beat, with an entire absence of the P wave. Atropine, gr. 1/50; ephedrine in doses varying from gr. 1/8 to gr. 1/2 t.d.s.; quinidine, in increasing doses from grs. 4 to grs. 7 t.d.s. were tried, but none had any effect on the main characteristics of the electrocardiogram.

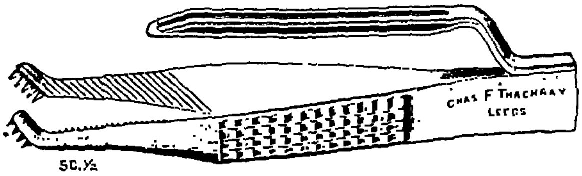
The result of the administration of adrenaline was, however, very striking. An electrocardiogram taken five minutes after the injection 0·5 c.cm. showed not only an increase in and a regularisation of the beat, but also revealed the missing P wave. Another picture taken ten minutes after the adrenaline showed the same features. After the effect of the adrenaline had worn off the electrocardiogram resumed its former characteristics.

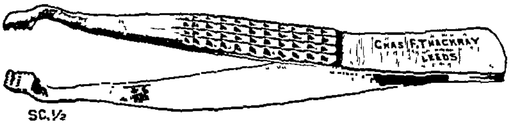
I have to acknowledge the kind assistance rendered by Dr. Isaac Harris in the elucidation of this case.

NEW INVENTIONS

FORCEPS FOR USE WITH MICHEL AND KIFA CLIPS

THE forceps here illustrated have been made for use with Michel clips, and particularly with the Kifa suture clips, and have proved very effective. The teeth of the holding forceps are after Childe's pattern, thus facilitating the approximation of the edges of the wound. The roughened areas on both the clip holder and the insertion forceps help the surgeon to obtain a firm grip of the skin edges, and to apply firmly to the skin whichever clip is used. The gallery holding the clips is the exact width of the Michel clips, is easy to load, and the strength of the spring, enabling the clips to be easily removed, prevents them from falling off or overriding each other, as frequently occurs. The suture forceps insert both varieties of clips easily, and remove the Kifa clips as easily, without pain to the patient. The several widths of the Kifa clips available particularly facilitate the closure of many upper abdominal and other wounds, where Michel clips tend to slip owing to the thickness of the skin.





They are made in rustless steel by Messrs. Chas. F. Thackray, Park-street, Leeds.

ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS AND GYNÆCOLOGY

THE meeting of this section on June 17th was devoted to a discussion on

Modern Methods of Alleviating Pain in Childbirth

The chair was occupied by Mr. VICTOR BONNEY, the President.

Mr. L. CARNAC RIVETT said that anæsthetics were discovered 100 years ago, and as long as 80 years ago Sir James Simpson used chloroform to lessen the pains due to childbirth. Twilight sleep enabled freedom from sensation to be continued for a long time, while nembutal and similar preparations could be used either by the mouth or intravenously, and provided powerful narcotics. Spinal anæsthesia, rectal ether, and avertin had been employed in suitable cases. It was something of a disgrace that the parturient woman could still say, in the words of the Psalmist, "The pains of Hell gat hold upon me." In quite 90 per cent. of normal deliveries it was possible to alleviate the labour pains. Three years ago he was able to bring the question to a practical issue. Lady (Rhys) Williams and Mrs. Baldwin started a fund to defray the cost of using anæsthetics in lying-in hospitals, and an offer from this fund was accepted by the management of Queen Charlotte's Hospital. The object was to help normal delivery.

VARIOUS ANÆSTHETICS REVIEWED

Nitrous oxide as an analgesic was practically ideal; as now administered it was operative for a long period, and was safe. It produced complete unconsciousness, which could be continued as long as the labour was likely to last, and was also susceptible of reinforcement by ether. Moreover, it did not inhibit uterine contractions, as did ether and chloroform. A drawback to nitrous oxide was that it could only be induced by a tight-fitting mask and by means of a heavy apparatus which required skilled manipulation.

This was an important consideration, since half the confinements in this country were conducted by midwives alone. Twilight sleep sometimes caused a complete cessation of the uterine contractions, though in time these were resumed; and Mr. Rivett had never had an infant death which he could ascribe to this cause. Sometimes the hyoscine acted as an excitant, and the woman became maniacal; and it was necessary to have an attendant present all through labour to vary the dose as required. Spinal and sacral anæsthesia were both too short to be of real value in normal delivery. Spinal analgesia, moreover, increased the contraction of the circular fibres, producing a violently contracting uterus with poor expulsive power. In rectal anæsthesia there was sometimes difficulty in keeping the drug in the rectum; it was liable to be expelled with the next pain. Ether was not suitable for normal labour; if given in small doses it was liable to cause excitement, if given for long periods bronchitis might ensue. Chloroform, the first anæsthetic to be used in labour, was still, in Mr. Rivett's view, the best, though not for obstetric operations. A very small quantity given when the patient felt a pain coming on sufficed to abolish the pains of labour. There was less likely to be a spasm of the muscles when the pain reflex was abolished. Under chloroform the average duration of the second stage, he found, was 45 minutes for a primipara, and under half an hour for multiparæ. Over 2000 women had had chloroform analgesia at Queen Charlotte's without untoward results. In a small proportion it was not successful in abolishing pain; in a very few there was excitement, probably because the anæsthesia was started at too late a stage. At the Middlesex Hospital, for the last six years, whiffs of chloroform had been given in labour cases as soon as the woman began to cry out because of the pains; no increase in unfavourable events which required forceps had occurred, nor were there any cases of perineal laceration.

CHLOROFORM IN CAPSULES

With regard to the economic aspect, if at least 90 per cent. of the 600,000 of the mothers' delivered in this country every year were to have the pains of labour abolished, the analgesic must be in the hands of midwives. Even if a doctor was engaged he could not spend 10 to 12 hours on each case. Doctors attended less than half the confinements in the country, midwives conducting most of the cases alone, and during most of the labour period the midwife had nothing to do. The method of using chloroform could soon be taught, and in intelligent hands there was no danger. Mr. Rivett had been trying small quantities of chloroform put up in ampoules, similar to those used for amyl nitrite, which were crushed into lint when ready for use. Each ampoule contained 20 m. of chloroform, and maintained analgesia for seven to ten minutes. Of 200 cases so treated at Middlesex Hospital, in 73 per cent. the result was good, in 20 per cent. fair; so that the method achieved some measure of success in 93 per cent. of cases. In six of the 200 cases there were perineal lacerations; in 5 per cent. there was post-partum hæmorrhage. There were no deaths.

Mr. Rivett expressed the hope that the section would pass a resolution requesting the Central Midwives Board to issue certificates to those midwives who had received sufficient instruction permitting them to administer light anæsthesia for normal deliveries. The barbiturates needed further investigation.

THE NEED FOR AN ANÆSTHETIST

Dr. I. W. MAGILL said that patients nowadays wished to know nothing about the birth of the child; but to obtain such complete amnesia with a drug was dangerous unless an anæsthetist was present to judge the progress of the case and to adapt the dose. Barbiturates certainly should not be handed out to midwives. Nembutal in a dosage of grs. 4½ might be successful, but might produce excitement and no amnesia. The best anæsthetic was a combination of nitrous oxide and oxygen, which was eliminated without leaving any deleterious effect to mother or child. Chloroform was a wonderful anæsthetic, and most of the trouble attributed to it was due to faulty methods of administration.

Dr. R. H. PARAMORE said that he had used spinal anæsthesia for three years for operative work, and in three cases of what he regarded as normal labour. It was important to curtail the second stage of labour and get over the obstructions to the birth of the child when the cervix was fully dilated. Spinal anæsthesia appealed to him as the anæsthetic for the use of the medical man.

Miss J. A. OLDAKER produced an analysis of 450 consecutive patients at the Royal Free Hospital who had sedatives during labour. Sedative drugs were *given as soon as the patient felt discomfort* during the contractions. Some 170 patients had no drug of the kind, either because the contractions were not very strong or painful, or because they were not admitted until the second stage. In 60 cases bromide and chloral (grs. 20–30 of each) were *given by the mouth and repeated. Opoidine* (1 c.cm.) and magnesium sulphate (2 c.cm.) were given together by intramuscular injection and there had been no experience of sepsis at the site of injection. In a certain number of cases forceps were necessary on account of ineffective uterine contractions in the second stage; some patients were given morphia gr. ¼. There had never been cause for anxiety because of the child's condition. 259 patients had intermittent nitrous oxide and oxygen anæsthesia during the whole of the second stage. When this was given the contractions were never diminished, but were sometimes increased. She had not yet sufficient data to enable her to express an opinion on the chloroform capsules.

Dr. H. E. BOYLE considered nitrous oxide and oxygen the ideal anæsthetic for childbirth, administered *by an anæsthetist who knew something of* obstetrics. He was against allowing midwives to use any dangerous drug. The efficacy of nitrous oxide and oxygen was increased by the judicious addition of CO_2.

THE ATTITUDE OF THE CENTRAL MIDWIVES BOARD

Dr. J. S. FAIRBAIRN said that a large proportion of working-class women delivered themselves, and it was highly desirable, from every point of view, that they should be relieved from prolonged pain. The chloroform capsule promised to be a most valuable general means to this end. The question had been under discussion at the Central Midwives Board. He understood that the London County Council were trying it out in some of their hospitals. The Central Midwives Board had asked the Section of Anæsthetics of the Royal Society of Medicine to express an opinion on the safety of the capsule in the hands of midwives. Small quantities of anæsthetic were required over a fairly long time, and to have a doctor in attendance during all that time was an expense that most women could not afford; moreover, the doctor could not neglect his other practice to that extent.

Dr. HERBERT CHARLES said his experience with chloroform in labour was that the pains were not felt and the mother remained conscious and could talk. Spinal anæsthesia was excellent for Cæsarean section, but not for the early stages of labour. He had the profoundest respect for chloroform in labour; it was a boon to the poor woman suffering in childbirth.

Dr. R. A. GIBBONS said he gave chloroform in the ordinary way with a mask in childbirth, and found that in small doses it kept the patient free from pain. No danger attended its use unless it were pushed. If there was exhaustion, a little ether could be given. He hoped it would be possible to sanction the use of chloroform capsules by midwives.

Mr. EARDLEY HOLLAND agreed there was a great future for chloroform capsules in the second stage of labour, but he doubted whether they were suitable for administration over many hours. One could better judge of the effects of anæsthetics among private than among hospital patients, for the former could be followed up. Different women felt labour pains with varying intensity according to their temperament. Much could be done without drugs by talking to the patient and reassuring her and urging her to relax and so help the birth. In the first stage of labour he relied a good deal on chloral, grs. 40, dissolved in a considerable volume of water being slowly sipped. This medication formed an excellent basis for scopolamine and morphine.

Mr. A. J. COPELAND thought that with the capsules of chloroform there should be supplied a slip giving a few warnings—e.g., to hold the capsule not less than two inches from the face, and to place no covering other than the lint or mask over the face, and to use not more than one capsule at a time. Special wards might be set aside to investigate the comparative effects of different anæsthetics in childbirth. He favoured the addition of oxygen whatever anæsthetic was used.

Mr. J. P. HEDLEY thought that, in however small doses it was given, chloroform was undesirable in the first stage of labour. An anxious woman got more excited if she had chloroform early, and if she were given more, which she would certainly demand, the force of the uterine contractions was diminished.

Dr. KELSON FORD said that if midwives generally were to be allowed to use chloroform capsules he did not know how the rural chemist was to determine whether anyone asking for them should be supplied. It would be safer if the medical man could authorise their use.

The PRESIDENT said the suggestion that the Central Midwives Board should take action in this matter was a pertinent one. He could endorse the view that there were many difficulties in the way of authorising midwives to use chloroform.

Mr. RIVETT, in his reply, said he regarded normal labour as labour in which the woman succeeded in delivering herself without extraneous assistance. He always regarded it as a disgrace if the perineum was injured. If ether were given for several hours there was a risk at least of bronchitis, possibly of pneumonia. The law was that if a person could be shown to be competent, and trouble arose, she could not be prosecuted for negligence, but if the person concerned was shown to be incompetent, prosecution might follow. The issue of the capsules would depend on the doctor in any particular case. Chloroform was not included in the schedule of dangerous drugs, but hyoscine was.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

AT a meeting of this society held at Manson House on June 16th, with Dr. G. CARMICHAEL LOW, the president, in the chair, the Manson medal was awarded to Prof. Theobald Smith, of New York, and was received on his behalf from the president by Dr. G. K. Strode, of the Rockefeller Foundation. A discussion on

Synthetic Antimalarial Remedies and Quinine

was opened by Colonel S. P. JAMES. The malaria commission of the League of Nations, he said, aimed at providing a cheap and abundant supply of a remedy which would limit attacks and prevent deaths from malaria by planting cinchona trees in malarious districts. The aim of chemotherapy was to provide a remedy for cases in which quinine was known to fail, a remedy which would supplement, but which would not replace quinine or injure the cinchona industry. Quinine might be effective with some strains of parasite, and synthetic drugs, such as plasmoquine, effective with others. Therapy must be studied not only in terms of the strain of parasite to be overcome but in terms of the different phases of each species of parasite recognised; plasmoquine had a selective action on gametocytes, but little effect on schizonts, while the opposite appeared to be true of quinine. The selective action of drugs indicated differences in the biological properties of the parasite in different phases. Therapy must also be studied in terms of the geographical distribution of strains, for the virulence of the parasite varied not only with the species but with different geographical strains of the same species. In some parts of Italy a more effective drug than quinine was already needed, and atebrin seemed to fulfil this need. Among a series of seven cases infected on the same day, five treated with atebrin were cured, while two treated with quinine were not cured. Contradictory observations on the properties of plasmoquine were probably due to the use of different geographical strains. With some strains plasmoquine prevented relapse. After infection with a Madagascar strain of benign tertian malaria, plasmoquine and quinine were found to be more effective in preventing recrudescence than plasmoquine alone. The tolerance or immunity acquired by the patient before treatment was begun were also factors to be taken into account in estimating the action of drugs, and the dose of infection, depending on the number of mosquito bites, also made a difference; even atebrin would not cure outright a severely infected case. Experiments were made with plasmoquine in the prevention of infection. With a dose of 0·06 g. of plasmoquine given daily for six days it had been found possible to prevent malignant tertian in every subject treated. No failures had been recorded with benign tertian until an experiment was made on nine or ten students at St. Mary's Hospital; the primary attack was prevented in every case, but five of the patients developed attacks of malaria between seven and nine months later. Plasmoquine was a causal prophylactic agent, but the dose necessary was too large to be taken for more than three or four days. A similar but less toxic drug was needed.

Dr. C. A. **Henry** reminded his hearers that the alkaloids of cinchona bark were quinine, quinidine, cinchonine, and cinchonidine. In their effect on malaria, he said, quinine and quinidine were about equal; cinchonine and cinchonidine were probably inferior to the other two. The malaria commission of the League of Nations had decided that it would be sufficient to provide a mixture of all the crystallizable alkaloids of cinchona bark instead of quinine, this preparation to be called totaquina, and to contain 70 per cent. of the crystallizable alkaloids, of which 15 per cent. must be quinine. Totaquine could be made in one of two ways; the product of the first method contained 77·9 per cent. of crystallizable alkaloids, of which 30·4 per cent. was quinine. The second product, made from manufacturers' residues, contained 78·5 per cent. of crystallizable alkaloids, of which only 20·7 per cent. was quinine, and more than 40 per cent. was cinchonine. The second product was far less effective than the first, but at the present time it was the only type available. The cinchona industry had been rationalised to make the supply meet the demand; 95 per cent. of the cinchona bark used was grown in Java. Suggestions were sometimes made that cinchona planting should be revived in the British Empire, but this would only reproduce the disorder of 20 years ago when too much bark was placed on the market.

Prof. N. H. **Swellengrebel** described an attempt carried out at Amsterdam to prevent the outbreak of fever and the appearance of benign tertian by protecting subjects with plasmoquine. Doses of 0·03 g. were given daily for six days, beginning on the day before exposure to infection. The attempt failed; all the patients except one developed malaria at the usual time, and the one who failed to do so developed an attack some months later. Of those who developed the primary attack, some were treated with plasmoquine, some with plasmoquine and quinine, and some with quinine only. All relapsed or else developed recurrences more than 24 weeks after the primary attack. Dr. Piebenga, working elsewhere in Holland, had reported a series of cases treated with quinine and plasmoquine in a large proportion of which there were no relapses or recurrences. Dr. Piebenga had been working with the home strain of benign tertian, using naturally infected mosquitoes. Prof. Swellengrebel said that in his own cases artificially infected mosquitoes were used, and the strain was the Madagascar strain of benign tertian obtained from England. The home strain was less reliable in causing malaria and was probably of a lower vitality than the Madagascar strain. The number of infecting bites in Piebenga's cases, moreover, was not known, but it was unlikely that they exceeded one bite per patient in that region; his own cases had averaged a large number of bites. The relapse-rate for Holland as a whole was 50 per cent.; the fact that 100 per cent. of Prof. Swellengrebel's experimental cases relapsed seemed to indicate that the strain of malaria used was exceptionally refractory to plasmoquine. His results did not contradict those of other observers, but only served to show that treatment with plasmoquine might break down where there were large numbers of infecting bites, or where the strain was particularly virulent.

Sir **Henry Dale** said that the method of testing antimalarial drugs had advanced; it was now possible to differentiate between the different phases of the parasite, so that the drug to be tested could be made to intervene at any stage.

Sir **David Prain** said that technical chemists used to interest themselves in the synthetic production, at a cheaper rate, of substances found in nature. They now followed another principle and attempted to provide a substitute which was an improvement on the natural substance. The idea was not a new one, but went back 600 years to a king of Castile, who shocked his priests by remarking that if he had been present at the creation he could have prevented many blunders. As soon as the chemist could provide the perfect substitute we should be able to dispense with cinchona, and we must already advise against any extension of the cinchona industry.

Dr. W. D. **Nicol** described the natural clinical course of 161 cases of benign tertian malaria which had been under observation for a year or more at Horton. They were infected with the Madagascar strain, and 140 developed fever at the end of the normal incubation period; 21 developed latent malaria 25 to 40 weeks after infection. In 110 cases the primary attack was terminated with quinine, in 18 with some quinine preparation, in 6 with plasmoquine, and in 6 with plasmoquine and quinine; among these, 29 had recrudesced within eight weeks, 13 relapsed between the eighth and the twenty-fourth week, and 39 recurred after the twenty-fourth week.

Dr. Philip Manson-Bahr mentioned a case of severe malignant tertian malaria with cerebral complications seen first on May 18th of this year. The patient was treated with one injection of quinine and then with atebrin for five days; he had made a good recovery, and appeared at the meeting in perfect health.

Prof. W. Schulemann said that it had never been the intention of workers at Elberfeld to produce a drug to contend with quinine. The aim was to produce new drugs which would give results which quinine could not achieve. It had been shown that in certain circumstances plasmoquine reduced relapses and recurrences; these findings needed confirmation with the same strains in tropical and subtropical countries. In subtertiary malaria plasmoquine did not appear to reduce the number of relapses, but the relapses with this strain were in any case few. In recent experiments made at Elberfeld by Dr. Kikuth on various species of avian malarial parasites it had been possible to study the action of drugs on separate phases in the life of plasmodia; he had found that atebrin acted on schizonts but not on gametocytes. These findings had been confirmed, but further prolonged experiments were needed. Quinine was not a causal prophylactic: it controlled clinical symptoms only during its administration. Colonel James, by giving 0·06 g. of plasmoquine for six days had prevented recurrence of attacks in 50 per cent. of his cases. Prof. Swellengrebel, using 0·03 g. for six days, had been unable to confirm these results. Probably the halving of the dose was sufficient to explain the discrepancy. As Colonel James had pointed out, the problem of malaria was becoming more and more complicated. It was not, however, necessary to test the virulence of every strain; laboratory results were not the only criterion, and the resistance of the host was an important factor in malarial infection. A detailed comparative investigation was needed to find out whether a strain of the parasite showed the same susceptibility to drugs in a native in the tropics as it did in a patient in a temperate zone. In order to get the best results with the drugs available we must take into account the variable susceptibility of the parasite to those drugs, and also its geographical origin. Atebrin and plasmoquine both had special properties, and clinicians must learn to choose the drug or the combination of drugs which would produce the best results in a given case. In order to get an idea of the value of the three drugs now available the coöperation of the laboratory and hospital with the general practitioner was needed. The ideal would be a single drug which was effective against every type and strain of the parasite, but in default of that we must learn to use correctly, and to develop, the weapons at our disposal.

Sir Malcolm Watson said that atebrin had been tried on a small series of cases in Malaya, and two out of four had relapsed. A single case treated with atebrin and plasmoquine had also relapsed. Experiments were now being performed on three groups of Malayan children, and results would probably be available in six months time. He thought there was evidence that the virulence of a strain might vary. Non-immune people entering an area where malaria was mild frequently became infected, and in turn infected the Malay population, with malaria which decimated both the newcomers and the residents. Presumably the virulence of the local strain had been increased by passage.

Sir Aldo Castellani thought plasmoquine curative, but less so than quinine. In acute pernicious cases he would advise the use of quinine in large intravenous and intramuscular doses rather than plasmoquine. In relapsing cases plasmoquine was useful when combined with quinine, but its special advantage lay in the treatment of patients who showed idiosyncrasy to quinine, and in black-water fever. Exceptionally, an attack of black-water might be started by plasmoquine. The value of synthetic drugs was that they provided a second weapon in addition to quinine.

Colonel James, in replying, said that he could not agree with Sir David Prain that synthetic drugs would affect the cinchona industry. Clinicians would continue to use quinine where it was the most useful drug, and the other remedies where they were applicable.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At a recent meeting of this society held in Leeds Dr. S. B. Herd (Liverpool) described a case of

Chorionepithelioma of the Broad Ligament

The patient, aged 48, gave a history of ten normal confinements and one abortion. She missed three periods, and then had continuous bleeding for three weeks. As the uterus was of the size of, and felt like, a 12 weeks' gestation, she was treated as a threatened abortion, but the bleeding did not completely stop.

When she was next seen the uterus was no bigger, but the interval after the last normal period was 24 weeks. A diagnosis of carneous mole was made, and the mole was expelled spontaneously. It was typically carneous except for a few minute vesicles in one area, and on microscopical examination there was evidence of hydatidiform degeneration in this area.

For six months there was menorrhagia (no intermenstrual bleeding), but she then bled constantly for a month. Careful examination under anæsthesia, and curettage, failed to reveal any sign of placental tissue or chorionepithelioma, and the irregular bleeding ceased for a further six months, the periods being regular but excessive. Finally, about 16 months after the expulsion of the mole, the patient presented herself with a history of further bleeding for one month, and neuralgic pain in the left hip and thigh for the same length of time. The Aschheim-Zondek test was strongly positive, and there was a hard fixed mass which *proved to be on the left broad ligament*, and to have no apparent connexion with the uterus although the wall of the bladder was partly invaded.

This case, said Dr. Herd, was of interest because of: (1) the comparatively long history; (2) absence of growth in the uterus; (3) doubt as to the origin of the growth in the broad ligament; and (4) question as to whether earlier operation would have saved the patient's life. While extension from a chorionepithelioma of the uterus was possible, the growth apparently arose as a primary malignant condition in the broad ligament.

Dr. Herd also showed a specimen of Epithelioma of the Vulva removed from a patient aged 25.

Toxæmia of Pregnancy

Prof. Carlton Oldfield described three unusual cases of toxæmia associated with pregnancy. The first case resembled "milk fever" or "bovine eclampsia." The patient was a primigravida, who, after a low forceps delivery of a healthy child, began to vomit on the third day. This continued, and the temperature rose to 101° F. on the following day, and there was epigastric pain and jaundice with development of coma. On the fourth day, routine treatment having failed to produce any improvement in the condition, inflation of both breasts with air was carried out, and two hours later the patient began to improve.

The other two cases were similar in that persistent vomiting ended fatally, and that both were in the first pregnancy. Also anorexia was a conspicuous symptom, and was a contributory cause of the exhaustion. One of these patients gave a history of neurosis, and had severe vomiting until the sixteenth week when this ceased, but 12 days later drowsiness followed by coma developed. In both cases the urine was negative for evidence of toxæmia, and in spite of treatment both patients died. Autopsy revealed signs of mild toxæmia with some liver damage in each case, but this was hardly sufficient to account for death. Prof. Oldfield considered that these three cases suggested that the conception of toxæmia of pregnancy originating in the ovum is probably erroneous.

Dr. C. G. Paine (Sheffield) read a paper on Colony Variation in Hæmolytic Streptococci and its Importance in Puerperal Sepsis Immunity.—Prof. M. J. Stewart and Prof. Carlton Oldfield showed a specimen of diffuse endometriosis of the body of the uterus, secondary tuberculous infection, and old bilateral tuberculous salpingitis, and also a specimen of liposarcoma of the broad ligament associated with spindle-celled sarcoma of the uterus.—Mr. A. Gough described a case of Carcinoma of the Fallopian Tube.

REVIEWS AND NOTICES OF BOOKS

Handbook of Tropical Fevers

By N. P. Jewell, M.D., D.P.H., F.R.C.S.I., European Hospital, Nairobi, Kenya; and W. H. Kauntze, M.D., D.P.H., Deputy Director of Laboratory Services, Kenya. With a foreword by A. T. Stanton, C.M.G., M.D., F.R.C.P., Chief Medical Adviser to the Secretary of State for the Colonies. London: Baillière, Tindall and Cox. 1932. Pp. 485. 16s.

In his foreword Dr. Stanton points out the close coöperation between clinician and laboratory worker which has characterised the study of tropical diseases. Manson himself combined in rare degree the qualities of observer and experimenter, and his methods have been diligently pursued by his disciples. This volume records the results of a combined study of tropical fevers in Kenya. Most of the more important fevers to be met with in the tropics are described, even those which have happily not yet appeared in Kenya, for example, melioidosis and Oroya fever, still far away, and yellow fever which is an imminent danger. The choice of matter cannot have been easy, because many fevers occur commonly in temperate regions as well as in the tropics, and in other diseases more specifically tropical pyrexia is only an occasional, though possibly a well-marked, symptom. A chapter on the enteric group of fevers in the tropics has been included, but none on pneumonia and pulmonary tuberculosis, though the prevalence and severity of these infections in the natives of Kenya is recorded. Though they name the various works on tropical diseases which have been consulted in preparing this volume, and especially record their indebtedness to Castellani, Gordon Thomson, Robertson, et al., for the many illustrations taken from those authors' works to embellish their own, and to Dr. R. G. Cochrane for assistance in the excellent chapter on leprosy, the authors have given more than a compilation, they have, in the 26 chapters, embodied the more important results of recent research and have treated their subject matter lucidly with evident carefulness and in a practical manner. Where more than one method of diagnosis and treatment is noted, that one is given at length which their own first-hand experience has taught them is the more suitable and more reliable. They have produced a volume which may well serve student and practitioner as a trustworthy introduction to any intensive study of tropical fevers. The book is handy, well printed, well indexed, and well illustrated, in so far as photomicrographs can ever illustrate.

A Text-book of Embryology

By Mary T. Harman, Ph.D., Professor of Zoology in the Kansas State College of Agriculture and Applied Science. London: Henry Kimpton. 1932. Pp. 476. 18s.

This book is at its best in the earlier chapters, dealing with more general questions and with the early changes in the sex cells. After this it shows a tendency, common to nearly all books of its type, to cover the ground with too little attention to detail. The result is failure to provide an orderly consecutive account of the subject; a serious student would find difficulty in acquiring coherent and satisfying ideas about any regional or organic development from such material. On the other hand, there is evidently a demand for books on embryology which aim no higher than the standard of ordinary examinations, and Prof. Harman's book is a complete and compact work within these limits. It is well produced and profusely illustrated.

Asthma and Hay Fever in Theory and Practice

By Arthur F. Coca, M.D., Matthew Walzer, M.D., and August A. Thommen, M.D. London: Baillière, Tindall and Cox. Pp. 851. 45s.

Publications on asthma and allergic diseases continue to appear in increasing number. This volume offers a comprehensive review of our knowledge of these conditions by three workers from Cornell University and Bellevue Hospital, N.Y. The first part, by A. F. Coca, is devoted to hypersensitiveness, anaphylaxis, and allergy. Much of it is taken up with the author's own researches, but since he refers to more than 370 articles from the literature he cannot be accused of ignoring the work of others. The term "atopy," here used to include asthma and hay-fever, is derived from the Greek atopia, a strange disease; the sensitising body present in the sera of hypersensitive persons is named "atopic reagin," also a strange sound to English readers. The terminology of "allergic" disorders is already puzzling, and the introduction of new names without explanation or discussion will hardly dispel the confusion of the general medical reader.

In the second and third parts of the book asthma and hay-fever are considered separately in great detail, a wealth of experimental and clinical data being supplied. Nearly 100 pages are devoted to "atopens and other excitants" which are held to range from animal emanations such as rabbit, cat, and horse hair, feathers, wool, and dust to almost every known type of foodstuff, including meat, fish, eggs, milk, nuts, vegetables, spices, chocolate, alcoholic and even soft drinks. The number of possible atopens is, in fact, so vast as to discourage those who have been hoping to get constant specific reactions to skin tests in asthma and allied conditions. The greater part of the section on hay-fever deals with botanical minutiæ about plants and pollens concerned in the causation of this condition. Over 1600 references are given in the bibliographies to Parts II. and III. This volume will take its place as a valuable work of reference for specialists, but is hardly one to which the physician will turn to refresh his knowledge of general principles.

Vision and Colour Vision

By R. A. Houston, M.A., D.Sc., Lecturer on Physical Optics in the University of Glasgow. London: Longmans, Green and Co. 1932. Pp. 234. 15*s*.

This book is a physical and mathematical approach to the complex problems of vision and colour vision; it is valuable not only for its critical analysis of recent work on the subject but also for the mass of original work it contains. The author questions such entrenched views as the duplicity theory of vision, holding that it is accepted for the simple reason that no other theory has been put forward—though Edridge-Green's view is given. Weber's law on the discrimination of intensity is demolished by a mathematical analysis which proves that its results represent nothing but a Gaussian curve of error. On colour vision the author is at one with all physicists in decrying introspective analysis, but the Young-Helmholtz theory dear to physicists does not escape unscathed. In fact, he advances cogent proof that mathematically it is untenable. The classification of the colour blind into deuteranopes and protoanopes is regarded as having descriptive value, but is seen as artificial when the colour blind are studied statistically. Houston's own view of colour blindness is that it is due to an irregularity in the working of retinal synapses, though he admits that the mode of action he postulates is hypothetical.

The book is a sound and provocative piece of work.

Flat-foot

By S. D. Fairweather, M.A., M.B., Ch.B. London: John Bale Sons, and Danielsson. 1932. Pp. 76. 7*s*. 6*d*.

In this little book Dr. Fairweather launches a severe attack upon the world in general for its stupidity in adding heels to its footwear. To this habit he attributes flat-foot and indeed almost all mechanical disabilities of the foot. He says that when heels are worn the outer part of the foot is removed from the ground and the weight rests on the heels and fore-part only. He says also that the centre of gravity of the body is thrown forward, and that to overcome this the muscles of the back, of the thigh, and of the legs are in a state of more or less tonic contraction; hence, in his view, come fatigue, often neurasthenia, and sometimes sciatica. A simple experiment devised by Mr. P. B. Roth lends no support to the theory that the centre of gravity is thrown forward by heels. He has shown that if a bare-footed woman stands on two adjacent weighing machines with the heels on one and the fore-feet on the other, two-thirds of her weight is found to fall on her heels, and one-third on her fore-feet; if the experiment is repeated with a woman wearing ordinary heeled shoes the proportion of her weight on either scale is unchanged. It is true that when cheap high-heeled shoes with weak shanks are worn the heels are raised and the weight rests only on the heels and the fore-part of the foot, but a well-constructed shoe gives as much support to the outer part of the foot as it would have if it were flat on the ground. Dr. Fairweather's arguments are not convincing.

The Heart and Spleen in Health and Disease

By G. Arbour Stephens, M.D., B.S., B.Sc. Lond., Consulting Cardiologist, King Edward VII. Welsh National Memorial Association; Consulting Physician, Cardigan and District Hospital, and Llandovery and Clydach Cottage Hospitals. London: H. K. Lewis and Co., Ltd. 1932. Pp. 139. 7*s*. 6*d*.

Dr. Arbour Stephens has for some years carried on research work, more particularly in connexion with calcium metabolism and disorders of the heart. In this book he brings together the main ideas underlying all this work. The first chapter describes his modified stethoscope, which he calls the "cardioscope," and restates the author's theory on the production of the heart sounds. The second chapter deals with blood pressure, more particularly the diastolic pressure which is renamed the "basic pressure," and supplies a description of a new method for arriving at this figure. In subsequent chapters reasons are given for associating the spleen closely with the heart and the circulatory system, and arguments are set out to prove that auricular fibrillation, flutter, and tachycardia are not separate entities, but 3 out of 24 possible stages in the same type of disordered action. Considerable space is devoted to a discussion of predisposition, which is defined as a definite state of disordered action or disease. The spleen is shown as the refitting shop for the corpuscles in connexion with the oxygenating function of the circulatory system. In the chapter devoted to acute rheumatism and chorea, particular stress is laid on the fact that these diseases occur in what is termed the "acid class." The author explains in detail why he considers that the wrong feeding of adults is responsible for much of the heart trouble arising in later life. He emphasises the importance of diagnosing heart disease early, and has found that in every case of acute inflammation of the tonsil examined the heart is disturbed, as shown by an alteration in the basic pressure. The teaching in the last chapter is described by the author as "full of difficulties and highly dangerous, but that is no reason why it should not be properly faced and studied," and this remark is not wholly inapplicable to the whole book.

Anatomy of the Nervous System

Fourth edition. By Stephen Walter Ranson, M.D., Ph.D., Professor of Neurology in Northwestern University Medical School, Chicago. London: W. B. Saunders Company. Pp. 478. 32*s*. 6*d*.

Prof. Ranson writes throughout for students of neurology working in laboratories and makes a consecutive story out of his material while arranging it to provide a work of reference of wide scope. We hope that in the next edition he will see his way to a less cavalier treatment of the transverse peduncular tract and its endings, but otherwise the information supplied is adequate. The present issue has an excellent new feature in the shape of a series of sections through the brain stem; these are being added now to many neurological works coming from America. Altogether a sound and useful book.

BELLE VUE SPA AND HOTEL

TREFRIW, NORTH WALES

The combination of medical treatment and comfortable residence amid beautiful scenery offers great attraction to visitors as well as patients.

Thirty bedrooms, magnificent lounges, billiard room, tennis court, eight and a half miles of salmon and trout fishing, and golf courses within easy reach. The new bath and treatment rooms within the Belle Vue Spa's grounds, recently opened by an eminent surgeon, are equipped with the most up-to-date apparatus for electrical treatment.

The Belle Vue Spa sulphur-iron water (ferrous sulphate), described by medical men as the purest and most highly concentrated in the world, is collected from an ancient Roman mine according to medical advice, so as to prevent any air coming in contact with the iron water.

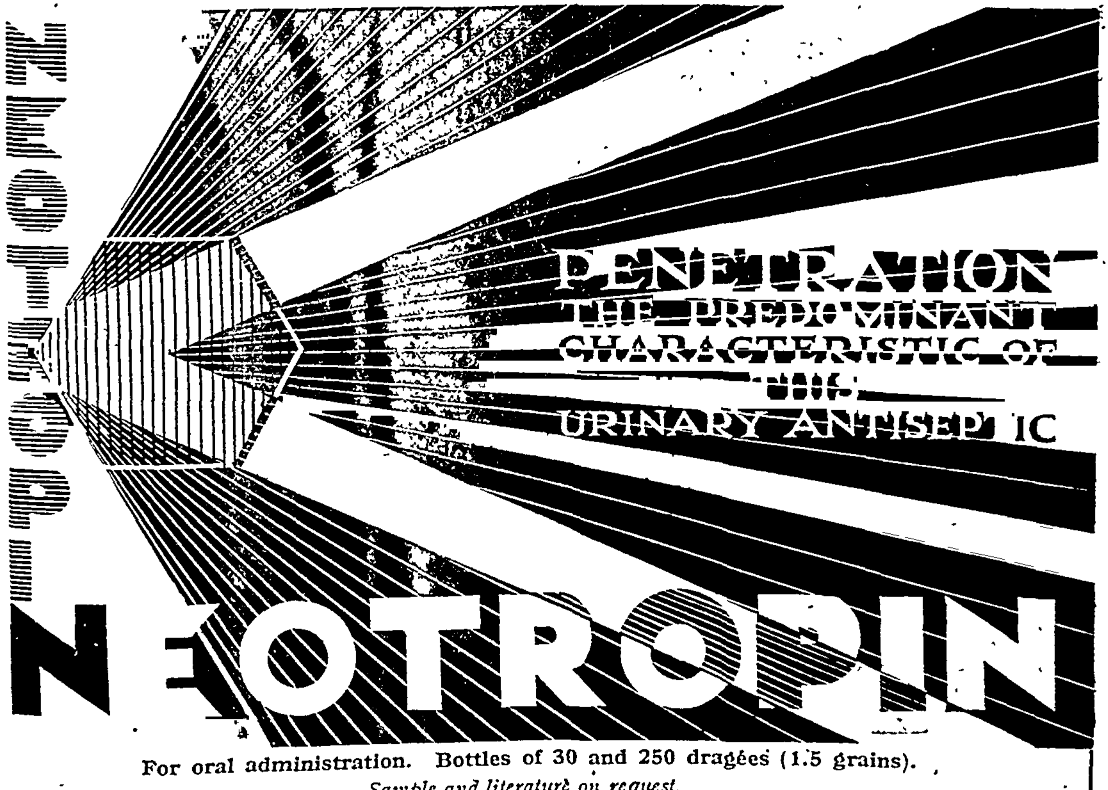
Sufferers from Rheumatoid Arthritis or Osteo-Arthritis in hips or knees, who have been bed-ridden for months or years and want to walk again without pain, can avail themselves of the Hoefftcke Ambulatory Extension Treatment.

Special facilities are provided for those requiring this treatment in the nursing wing under medical supervision.

This treatment has been favourably commented upon by many eminent medical men in the Medical Journals.

See *The Medical Press and Circular*, April 27th, 1932, pp. 348–351: Ambulatory Treatment of Fractures and Diseased Joints by the Hoefftcke Extension Splint.

For reprints and further particulars apply The Secretary, Belle Vue Spa, Trefriw, N. Wales, or Mr. C. A. Hoefftcke, 7, Harley Street, London, W.1.



For oral administration. Bottles of 30 and 250 dragées (1.5 grains).

Sample and literature on request.

SCHERING LIMITED, 3, LLOYD'S AVENUE, LONDON, E.C.3.

"ACRIFLAVINE"

(May & Baker)

Acriflavine is a powerful antiseptic possessing very low toxicity. It is practically non-irritant to the tissues in the dilutions generally employed and its activity is rather enhanced than diminished in the presence of the body fluids.

Acriflavine solution is the ideal antiseptic for the treatment of infected wounds and is the standard preparation for irrigation in gonorrhœa. Other important applications are in local septic skin conditions, tonsillitis, gingivitis, septicæmia and septic conditions generally.

Descriptive literature on request.

THE UNAUTHORISED OPERATION

The litigation to which surgeons are exposed is usually based on an allegation of negligence. A recent case is a reminder that they are also liable to be sued for trespass to the person if it can be proved that, in performing an operation, they have exceeded the authority given by the patient. Three statements may here be quoted from "The Conduct of Medical Practice." A patient who consults a doctor gives implied consent that the doctor shall be entitled to do all such acts as he considers reasonably necessary for discharging the duty of diagnosis, regard being had to the state of medical knowledge and to his own personal experience. A practitioner who proposes any dangerous or painful act or any act causing, if unsuccessful, a permanent disability, should supply the patient with the material information to enable him to give or withhold consent. Finally a surgeon, though circumstances may make it difficult to attain the ideal of having patients' written consent to the operations performed, may expose himself to liability in damages for trespass to the person (a legal classification which includes assault and battery) if he exceeds his authority.

These general observations will serve as introduction to an examination of the High Court action brought last week against the Royal Surrey County Hospital and the surgeon in charge of its gynæcological department. Damages were claimed on the several grounds of negligence, breach of contract, and trespass to the person. The plaintiff complained that the surgeon, contrary to her instructions and wishes, performed on her at the hospital the major operation of removing her uterus, though she had consented only to the minor operation of curettage. As will be seen from the report on p. 1377, the jury found that her complaint was justified. Her medical attendant had written a letter to the hospital conveying her refusal to undergo the major operation. This letter, from some cause inadequately explained, reached the hospital but was not brought to the surgeon's notice. There was thus an error of hospital administration which made it almost inevitable that the plaintiff would succeed in her claim, though there was some evidence (strongly denied by the plaintiff) that she was aware of the nature of the operation about to be performed and that she made no objection. Where a claim of this kind succeeds, a jury may easily award substantial damages. The facts of the case, however, were capable of being interpreted as an occasion for congratulation rather than of heavy compensation. For the patient suffered from epileptic fits which had become increasingly serious during recent pregnancies.

These proceedings were instructive both on the question of a surgeon's authority and on the question of eugenics. It is essential to keep these two points apart. An official inquiry into sterilisation is proceeding but it will be a long time before the law is changed in the direction of compulsory sterilisation against the patient's wish. The law, as Lord Hewart explained to the jury, does not enable a surgeon to say "If I had my way, I would sterilise the patient," and then to go on and perform the operation against the patient's desire. It is one thing to say that, if the patient had consented, the operation would have been proper; it is quite another thing to say that, in the absence of her consent and in contradiction of her expressed wishes, the operation was proper. The case is also important on the question of hospital administration; a hospital cannot afford such oversights as the loss of an important letter conveying the patient's precise wishes. In a proper case the damages might have been heavy. We may note, too, Sir Henry Simson's answer (given during cross-examination) that, if his attention were drawn to a discrepancy in papers relating to a patient on whom he was about to operate, he would report the matter to the hospital authorities and see that the patient was asked about it, or he would ask the patient himself.

◆

SEAMEN IN CARGO SHIPS

The Shipping Federation, which is the chief association of shipowners, decided in May, 1929, to set up a committee to work out a standard accommodation suitable for seamen on cargo steamers, and chose for this purpose seven marine superintendents and two shipbuilders, who had the advantage of calling on Dr. C. White, M.O.H. of the Port of London, for advice in regard to ventilation and hygiene generally. In the report[1] of that committee, which has now been issued, the main feature is a definite proposal, with plan, for the crew's accommodation on a cargo steamer of 6000 tons, taken as a type example, manned by 12 sailors and 12 firemen. Two striking advances catch the eye at once. The first is that the men are to be housed aft, in a deckhouse under the poop, where they will have better lighting and ventilation, less risk of injury in case of collision, less danger and discomfort in heavy weather; also, with the galley now more accessible, they will get their food hotter and more reviving just when they want its comfort most. The second, an even greater improvement, is the proposed increase of the height between decks from the statutory 6 ft. to 7 ft. 9 in., which will, as the committee remarks, facilitate ventilation, and, if we read the plan aright, will give to each man in his sleeping quarters 150 cubic feet instead of the 72 now the minimum there, besides another 100 cubic feet with which he seems to be provided in the messroom. That they have made this material advance is greatly to the credit of the committee. A number of other small but useful proposals are evidence of the increasing interest taken by marine superintendents in the comfort of the men, now that attention has been focused upon them. Thus, to safeguard the privacy of the crew, a separate water-closet is to be provided for dock labourers employed on board; a new container for bringing food down hot from the galley is being contrived, enamel paint is thought of for crew spaces (remember this is on cargo ships), while mosquito-screening of doors and windows of ships in the tropics, an isolation hospital for ships with more than 50 of a crew, and a splash-guard for the outer ends of soil-pipes, will all increase the comfort of the men. It is a pity the committee has not had more generous ideas about fresh water and hot-water supply to lavatories; few material things raise a man's self-respect, and make discipline more endurable to him, than opportunities to keep himself clean. The committee complain there are no trustworthy statistics about the health of seamen. They did refer to Surg. Capt. T. B. SHAW's book on "Naval Hygiene," but did they consult the Admiralty? Much must be known there, and at least why, with the Army authorities, they decided to allot 200 cubic feet of space to each man on a transport ship.

---

[1] From the Secretary of the Shipping Federation, 52, Leadenhall-street, London, E.C.3.

The report shows a tendency to blame all the ill-health of seamen on their experiences ashore, which are thought to neutralise the effect of the good food the men get on board. Certainly the food has been good since Mr. LLOYD GEORGE, then President of the Board of Trade, piloted through Parliament the Merchant Shipping Act of 1906, requiring ships' cooks to be certificated, provisions put on board to be inspected as to quality, and issued in statutory amount. Not until then had shipowners any reason to be proud of the diet of the crews of cargo steamers. One cannot help a feeling of regret that this committee was not in being 30 years ago, when Dr. W. COLLINGRIDGE's famous lecture on Practical Points in the Hygiene of Ships was delivered[2] before the Shipmaster's Society of London, and shipowners were better off and seamen better employed. When we begin again to build ships, and along the lines of this report, the Federation will find that its ships are manned by healthier and more contented seamen.

TUBERCLE AND PSYCHE

Dr. ERICH EBSTEIN, whose death last year in the early fifties cut short a remarkable literary career, left material for a series of short pathological studies ("pathographische Skizzen") of famous people who have suffered from tuberculosis. He had completed more than fifty of these studies, which range from JOHN CALVIN to EUGENE O'NEILL, and these have been collected in a posthumous work, which includes also a short historical account of the treatment of tuberculosis at spa and sanatorium, and a list of works on psychology and psychiatry in relation to tuberculosis. Prof. G. B. GRUBER, of Göttingen, has contributed an introduction entitled "Tuberkulose als Schicksal," which gives a title to the book.[3]

Among the many psychological reactions to tuberculosis Prof. GRUBER recognises those of the two fundamental types of KRETSCHMER's classification—the reaction of the cyclothymic and the schizothymic man. EBSTEIN's character studies illustrate these types and others less clearly defined. There are men with warm sympathetic reactions to life and those whose general outlook is austere and gloomy. The names of many of the men and women are world famous—among them for example are SCHILLER, GOETHE, CHOPIN, and ROUSSEAU; a few are little known outside special circles. The three Englishmen included are AUBREY BEARDSLEY, JOHN KEATS, and LAURENCE STERNE. A list of 80 names of famous consumptives whose lives are not dealt with biographically is appended, and in this list the BRONTË sisters, OLIVER GOLDSMITH, and ROBERT LOUIS STEVENSON are mentioned. It is regrettable that Dr. EBSTEIN did not select STEVENSON for one of his illuminating studies in view of some possible difficulties and doubts in the diagnosis of his chronic illness. The list, long as it is, is by no means complete; the most learned encyclopædist could hardly make it so. But the names recorded are startling enough to show how the mind of man can rise above physical disability. How far tuberculosis is unique in this respect, and whether there is, after all, a special temperament associated with tuberculosis is another matter. Amongst the chronic diseases which last long and affect for good or ill a man's outlook on life—chronic rheumatism, valvular disease, blindness, deafness, and so on—tuberculosis is peculiar in at least one respect: the frequent bouts of toxæmia, which alternately stimulate and depress mental activity. This is hardly, however, sufficiently distinctive a characteristic to place tuberculosis in a class apart, for the difference may be one of degree rather than of kind. The considerable literature which has accumulated suggests at least that there is a fascination about the mental reaction of the tuberculous subject, and the possibility that it is classifiable. Dr. EBSTEIN has not been ambitious; his book is not a philosophical treatise, but rather an elaboration of the point of view expressed in a book entitled "The Fighters of Fate," published in America some three or four years ago by J. A. MYERS; that the victim of tuberculosis must either meet his fate bravely and compensate for his disability or must go under. Neither Dr. EBSTEIN's sketches nor Prof. GRUBER's introduction are of the morbidly inquisitive order which will encourage a sentimental introversion in the mind of the reader; they are serious attempts to understand a problem which will always have a fascination for medical men. It is interesting to find how large a part Davos has played in the lives of the last and of this generation of consumptives. This resort figures again and again in the biographies. The study of tuberculosis is enriched too, from time to time, by vivid descriptions of the disease, such as those of the poet KLABUND (Alfred Henschke). A small collection of portraits is included. None of them is quite so striking as the famous self-portrait of LAENNEC at Kerlouarnec, reproduced in Sir WILLIAM HALE-WHITE's biography.

[3] Tuberkulose als Schicksal. By Dr. Erich Ebstein. With an introduction by Georg B. Gruber. Stuttgart: Ferdinand Enke. 1932. Pp. 184. RM.6.50.

The character sketches are set out in a scholarly shion, with due references to authorities and proof the diagnosis of tuberculosis wherever this is btainable. All of them are free from sentientality and none strives after emotional effect. hile this is a book which physicians will be glad possess, we trust it will find no imitators. To ave these things faithfully recorded once is ough.

PREPARATION FOR MARRIAGE

When, seven years ago, the National Society r Combating Venereal Diseases decided to become he British Social Hygiene Council the change of ame signified more than the expansion of the reventive aspect of their activities. It was the tcome of a growing conviction that neither enereal disease, nor any other evil associated ith ignorance of the ethics and æsthetics of sex, ill be eliminated until a higher standard of x conduct can be achieved. Both the common enereal diseases are contagious, and the first sk in the successful organisation of a campaign o check their spread had to be the breaking down the assumption, then generally held by the he public, that the primary duty of the family ractitioner was to hush up their incidence, and he secondary to take such discreet steps as would elp the patient back to health, if this could be one, without betraying his guilt or ill-luck. It is ecoming unfashionable now to blame the Victorians r an attitude of reticence about matters of sex o which many wish to return: but reaction against ost-war freedom of speech and action will hardly e allowed to mask the discoveries, physiological nd psychological, which have changed the outlook f educated men, and especially women, towards sex fe. These have not hitherto been embodied in text-books designed for the laity, nor are they easy o define or explain; but the British Social ygiene Council have now, with logical courage, ursued their study from the problems of dolescence to the adjustments required from person of either sex who contemplates marriage. In a foreword to a handbook[1] which has been repared by a special committee on behalf of the Council, the Bishop of Liverpool points out that many marriages have been wrecked, and others made less successful than they might have been, for lack of knowledge which some married folks never possess and others learn too late. The book as originally planned was to be a symposium of the views of different specialists: but the result proved to be a collection of essays which lacked cohesion, and had the even more serious defect of a chilly detachment from the difficulties which beset individual men and women.

It was therefore decided to entrust the collation of material to an editor who, while aiming at an unprejudiced exposition, admits the difficulty in a disarming preliminary chapter. Mr. Kenneth Walker sets out with candour and precision such of his personal reactions as may help the reader to assess and discount his bias, and proceeds to discuss in order the place of marriage in human life, the essentials of marriage and family, courtship, sexual intercourse, adjustment in marriage, children, fertility and sterility, birth control, continence, and aberrations of sex. A last chapter is headed Advice to Advisers, and is followed by a glossary of scientific terms, a classified bibliography, and a full index. The desire to provide a basis broad enough to make the work acceptable in widely different circles has limited its scope, but a constructive philosophy remains. For example, the theory that mankind has ever been free to give play to his sexual instincts untrammelled by social restrictions is held to be unsupported by anthropological research; the sad idea of the woman as the passive and enduring partner in sexual relations is dismissed as obsolescent; and the family is hailed as the accepted ideal of a social unit, whose stability is essential to the preservation of human society. Respect for the family is indeed the theme which pervades the work. Thus, the widespread taboo against incest is traced, not to eugenic considerations, but to the need felt by nearly all peoples to prevent the disintegration of the family, sexual interest between its members being incompatible with the emotional and social bonds on which its cohesion depends. The section on courtship includes a pertinent discussion of the disappointments associated with trial marriages and with temporary unions among the intellectuals—a self-attributed nickname. Jealousy and possessiveness, which by mutual compact had been excluded from the ménage, suddenly appear, and complete freedom of action without emotional conflict is found in practice to be impossible.

In such a well-balanced survey a few unimportant exaggerations are regrettable. For example, the facts that certain occupations under the government are closed to married women, or that the income-tax paid by two unmarried persons is less than that paid on the joint income of man and wife are hardly likely to cause a significant increase, for purely economic reasons, in the number of illicit unions among couples who would otherwise marry; and the generalisation that "men move slowly along the road of reason; women, like arrows, fly straight to the mark" sounds like a breath from a pre-Freudian world. But such anachronisms are rare, and the work will be welcomed as a printed exposition of ascertained facts and of recognised gaps in our knowledge. It is shaped to supply accepted information rather than material for promotion of any cult or code, and some sections, notably those on heredity and fertility, fulfil this aim; in others, for example, those on continence or sex aberration, the positive knowledge at present available is too meagre to afford the basis for useful advice unless the reader can supplement it from his own spiritual or worldly experience. This very limitation shows the real scope and value of this work. It will be useful to those who have a strong urge to give help and advice, and are already partially equipped to do so.

ANNOTATIONS

THE I.M.S.

THE annual dinner of the Indian Medical Service this year was in the nature of a dramatic function, for it was presided over by the Director-General of the Service, Major-General J. W. D. Megaw in England on leave, and attended, as principal guest, by Sir Samuel Hoare, the Secretary of State for India. These two high officials spoke without reserve on how things are with the much discussed Service, and on how things may be with it, and with the vast Empire to which it ministers, in the days to come. And the message which they delivered from their different angles was one of reasoned optimism. The Service is obtaining excellent recruits, good relations obtain between the Indian and the European members of the Service, and their united front is everywhere resisting the innumerable attacks of disease. When General Megaw said the problem of India was essentially biological he was being literal not epigrammatic, and when Sir Samuel Hoare prophesied that the future benefits to be conferred on India by scientific medicine would rival the benefits of the past he was not rhetorical but speaking from figures.

ESSENTIAL HÆMATURIA

THE condition described as essential hæmaturia, although unsatisfactory from the point of view of diagnosis, is always of interest clinically. A paper by Guy L. Hunner [1] presents his original views and deals briefly with the relationship of ureteral stricture to hæmaturia in general. Of a series of 200 cases of hæmaturia, he says, stricture of the ureter was found in 174, while in 22 ureteric examination was not made because the bleeding was from the bladder or because investigation was refused; in the remaining four cases no ureteric stricture was discovered. Of the 174 cases with ureteral stricture other possible or probable causes of hæmaturia were found as follows: stone in the upper urinary tract 37, tuberculosis 8, renal tumour 2, elusive ulcer 13, and pyogenic cystitis or ulcer 15, thus reducing the number of cases to 99. This list is further reduced to 27, "as representing those patients whose bleeding was so profuse or so prolonged that the most critical could not deny them the usual classification under idiopathic or essential hæmaturia." Hunner believes that these cases are almost all due to ureteral stricture with its common background of focal infection. He attributes the bleeding to a pyelovenous backflow caused by the stricture, and possibly due to rupture of one of the large veins of the inner arcuate system. The prompt cessation of bleeding as soon as dilatation gives good ureteral drainage supports the relationship between stricture and hæmorrhage, and corresponds with experimental work showing that the relief of pressure is rarely, if ever, followed by hæmorrhage. In 18 of the 27 cases of essential hæmaturia the results obtained from ureteral dilatation and attention to local infection were ideal, and most of the remaining nine were definitely improved. Apart from essential hæmaturia, the belief is expressed that hydronephrosis, renal infections, renal and ureteral calculus, and renal tuberculosis are all largely due to a ureteral stricture. In considering the whole 174 cases of ureteric stricture with hæmaturia, only two were without other symptoms. The commonest of the associated complaints were of bladder symptoms, pain in the region of the kidney, pain in the lower pelvis, backache, and gastro-intestinal symptoms; these symptoms were usually relieved by ureteral dilatation. Hunner mentioned that in the past leading urologists had shown indifference to his work, but in the discussion following his paper it was highly spoken of by N. P. Rathbun and H. S. Jeck, and by O. S. Lowsley, who had himself suffered from ureteral stricture and been relieved by dilatation.

SCOTTISH HOSPITAL SERVICES

NOT the least interesting and, at this time of transition, not the least important section of the report [1] of the Department of Health for Scotland, covering the year 1931, is that which deals with the hospital services in that country. When the department came to consider the application of the Local Government (Scotland) Act of 1929 it was at once faced with the urgent need of coordination between the hospital activities of neighbouring authorities. Under the old system of local government there were in Scotland well over 1000 potential hospital authorities, ranging from county to parish councils, and a survey of the ground left an irresistible impression of the wastefulness of the present distribution of institutions in scattered units, too small to support a proper equipment of staff and material, and multiplying overhead charges. One of the worst results is that in some areas where a poor-house is jointly controlled by a number of authorities in combination, the medical work has remained in isolation, more or less completely dissociated from the public health organisation of any of the combined authorities, and only vaguely associated, if associated at all, with the responsibility of any medical officer of health.

The obvious remedy for this highly unsatisfactory state of things is to select for development such of the existing hospitals as are suitable for expansion with regard to situation and local possibilities, including accessibility to specialists and general practitioners. It is pointed out that this does not necessarily imply the closing of small hospitals which cannot justifiably be developed. They may continue to be used pending enlargements elsewhere, employed temporarily for convalescents, as children's homes, or for chronic or other sick persons now accommodated in mixed poor-houses. In these poor-houses the standard of treatment is low. The buildings are out of date, lighting, warming, and ventilation are defective, while the mixture of purposes served in such institutions produces "difficulties almost insuperable." Since their occupants have now to be lifted out of the poor-law and given the benefits of the whole hospital service of the area, there will have to be removals to appropriate hospitals, with the result that, in time, the poor-house hospital will cease to exist. Meanwhile, it is suggested that the medical officer of one of the combined authorities should exercise general administrative supervision as a means of remedying existing defects.

This work of comprehension and coördination must necessarily occupy much time, but the department is planning on wide lines with a view to every development embracing the whole hospital policy, not only of the council immediately concerned but usually of the councils of neighbouring areas. It is stated emphatically that the proposals of any town or county council must be related to the needs of the adjacent areas. Thus, not only are large units secured, but the facilities ovided by the voluntary hospitals are carefully ken into account. Even where local authorities ive powers of reorganisation and expansion under d statutes which absolve them from the requirement formal consultations with the voluntary institutions, ey are nevertheless being advised to observe the tter of Section 27 of the 1929 Act. The report, which cludes an account of the progress already made wards getting the new system to work, insists rongly upon the necessity for coöperation with the luntary hospitals for many purposes, "including edical teaching and research." No harm would ive been done by an even more pronounced insistence on this point, in view of the rapidly growing portance of that preventive and curative work which based upon research in the hospital laboratory.

PROSTATIC TECHNIQUE

Urologists are making every effort to remove ostatectomy from the category of septic operations, d a paper by Mr. H. P. Devine [1] contains many luable suggestions about how this may be done. e points out that the dangers of sepsis and hæmorage are partly due to the fact that the prostate shelled out blindly rather than dissected away om its bed. If, however, a satisfactory approach obtained, there is no reason why the prostate ould not be dissected away, with vessels tied as ey are divided, torn mucous membrane removed, d the cuff of divided mucous membrane sutured the prostatic bed. In order that this operation ay be carried out, he uses the well-known retractor earing his name, which has been modified especially fit the needs of prostatic and bladder surgery. wo of the blades which hold the bladder wall apart re fitted with small lamps placed in the middle of poons; these spoons serve both as reflectors and etractors. During the operation the blood is drawn way through a suction tube fixed to the frame and erminating in the lowest spoon. By this means and ith the patient in the exaggerated Trendelenburg osition, the removal of a prostate can be easily arried out under full visual control. In order that epsis may be avoided, changes must be effected not nly in operative but in post-operative technique. he latter usually suffers from the disadvantage hat continuous contact of the wound with urine nterferes with the process of healing. Therefore in he post-operative treatment of prostatectomy every ffort should be made to have as little urine as ossible in contact with the prostatic cavity. To chieve this, a rubber tube with many perforations n its lower end is inserted as far as the cavity. Into his is fitted a smaller metal tube, whose end is lowered ntil it is just touching the mucosa. This aspirating ube is kept in position by means of an adjustable crew on a circular metal plate lying over the abdomen. Suction is provided by a water pump attached to a urface tube. After seven or eight days, when the pace of Retzius is sealed off, the end of the aspirating tube is raised so as to lie just within the bladder. By these means Devine claims that it is possible to keep the bladder free from urine till granulation tissue has formed to provide a protection for the prostatic wound. The great quantity of air which is aspirated over the wounds assists in keeping them dry, clean, and healthy. He states that this method has been in routine use for over 15 years, and that practically it has been found to be a great advance in prostatic technique. The only criticism that can be made of it is that aspiration methods require a great deal of attention, and that what is undoubtedly excellent in theory sometimes breaks down in a busy hospital practice.

SANATORIUMS OR "TUBERCULOSIS HOMES"?

The comparative merits of the different forms of tuberculosis institution are being keenly debated at the present time in Norway, where two main types already exist. The one is represented by the large sanatoriums staffed by specialists, the other by the numerous small "tuberculosis homes" which are dotted all over the country. The latter are usually in the charge of a non-resident doctor, the local medical officer of health, or some equivalent. These unpretentious homes cost comparatively little per bed, and they are an invaluable refuge to patients who are in an advanced and incurable stage of the disease, and who wish to spend their latter days near home, without being a burden or danger to friends and relations. The homes have, in fact, become such a valuable and integral part of the administrative tuberculosis machinery in Norway that some of their over-zealous friends have been tempted to set them up as competitors of, instead of as auxiliaries to, the large sanatorium, the building and running of which is undoubtedly costly. A corrective to this movement is to be found in a singularly convincing and logical exposé by Dr. Cathrine Hambro.[1] As she points out, treatment of the tuberculous has the double aim of rendering them fit for work and non-infectious; it is by these two standards that the efficacy of any therapeutic system must be judged. To form an estimate of the value of treatment by specialists in a sanatorium, she has studied the records of 205 patients given sanatorium treatment between 1925 and 1928 and kept under observation, with only about five exceptions, till January, 1932. All, with three exceptions, were sputum-positive, and all were selected for pneumothorax treatment. It could not be carried out in 45 cases, and not more than one of these 45 patients achieved both fitness for work and non-infectiousness—this only after prolonged conservative treatment. Among the 160 patients in whom a pneumothorax could be induced, there were as many as 63 who ceased to be infectious and achieved complete fitness for work. Another 20 also ceased to be infectious and achieved a certain degree of fitness for work. Three other patients ceased to be infectious, but could not work. It will thus be seen that more than 50 per cent. of these pneumothorax-treated patients were restored to complete or partial fitness for work, and had ceased to be dangerous to their surroundings. Tuberculosis homes do not and, according to Dr. Hambro, should not attempt such therapeutic results. They should rather be clearing stations from which suitable potential pneumothorax cases should be sent to the large sanatoriums. It has, however, been suggested that the visiting physicians attached to tuberculosis homes should qualify themselves in artificial pneumothorax technique by a residence of six months at a sanatorium. Dr. Hambro is very doubtful as to the standard of efficiency likely to be reached by such a six months' stay; and (what is even more important) the medical officer of health who would like to convert his 40-bed tuberculosis home into a pneumothorax-inducing sanatorium would find an average of three hours work a day not too much for the needs of his institution. Few medical officers of health could possibly spare so much time in view of the many other claims upon them. Dr. Hambro concludes that Norway is probably sufficiently well provided with children's homes, and more or less adequately with tuberculosis homes, whereas the shortage of public sanatorium beds entails a delay of three or four months on the waiting lists. There is not, in fact, half a sanatorium bed for every yearly death from pulmonary tuberculosis. The solutions which Norway will ultimately find to these administrative problems will assuredly be of interest to the world at large, for most countries are at present facing the same or similar problems.

DANGEROUS DRUG TRAFFIC IN EGYPT

Within the last three years, under T. W. Russell Pasha's direction, the Central Narcotics Intelligence Bureau of the Egyptian Government has shown how much can be accomplished, both nationally and internationally, with zeal and determination in exposing and restricting illicit trade in drugs of addiction. It was reported to the last meeting of the Advisory Committee on Opium at Geneva that while in 1928–29 there were some 500,000 addicts among a population of 14,000,000 there are now fewer than 150,000; while convictions for offences under the Narcotics Act have fallen from 10,294 in 1930 to 5571 in 1931. Heroin is no longer imported in bulk into Egypt, though a large number of small consignments are still introduced. Hashish, which has only recently been added to the list of dangerous drugs, nevertheless claims many victims, and it is estimated that there are in Egypt no fewer than 282,000 hashish addicts! Russell Pasha has repeatedly called attention to the fact that under Egyptian legislation traffickers of foreign nationality cannot be proceeded against, otherwise the illicit traffic in that country would, he holds, by now have been very largely reduced. One of his most striking coups has been the conviction on June 15th of Mohamed Mustapha Nafei, the head of the greatest and most unscrupulous of the smuggling organisations in the Levant. His agents were widespread, ships and motor-cars conveyed the contraband goods to hiding places for storage, a chemical laboratory was maintained at Cairo, respectable capitalists were inveigled into the business, and police and soldiers had been bribed and corrupted. Caught at last, Mohamed Mustapha Nafei was sentenced to five years' imprisonment and fined £E.1000, while four of his confederates at the same time received similar exemplary sentences. Russell Pasha has set an example to some of the more lethargic signatories of the opium conventions in combating what he has termed "the ghastly side of narcotic addiction."

HERTZIAN-WAVE THERAPY

A method of procuring thermotherapy which has been little tried in this country is the use of short electro-magnetic (Hertzian) waves. Their action on the body and indications for their application are set out in a monograph[1] by Drs. J. Saidman and R. Cahen, in which the physical and electro-technical principles underlying the production of currents of extremely high frequency through the agency of the triode valve are enunciated. The authors regard most of the biological effects that follow exposure of the body to short Hertzian waves as due to the heat produced in the tissues, but they discuss the possibility of some other action of the waves and speak of their "quasi-specific" action in the treatment of the pain accompanying neuritis and neuralgia. The use of these waves in the production of the so-called therapeutic fever and the treatment of general paralysis is described. The technique does not seem to be elaborate.

When the current from the ordinary diathermy machine is employed for heating the tissues the electrodes are placed in contact with the body. If, however, the machine is constructed to produce current of much higher frequency the electrodes can be covered with insulating material and placed at a little distance from the body; the region of the body between the electrodes will be heated. The rise of temperature is attributed to the action of the short electro-magnetic waves to which the tissues are subjected. Those who are interested in the progress of diathermy and diathermotherapy will want to know what may be gained by the use of electro-magnetic waves for the purpose of heating the body and treating disease. The authors maintain that the deep regions can be heated to a higher degree than that which can be obtained with the diathermy current, and suggest that the biological effects brought about by the waves are *not wholly due to the production of heat*. The fact that the deep-lying organs of the abdomen can be heated only very slightly by the diathermy current is recognised, but absolute proof that they are heated by these waves has not yet been obtained and it would be even more difficult to prove the thesis that the biological effects of exposure to electro-magnetic waves are due, in part, to some physical change other than the elevation of the temperature of the tissues. One advantage of the employment of the waves in place of the diathermy current is however evident. The electrodes can be applied over the clothes. This not only saves the time spent in arranging electrodes in perfect apposition with the uncovered skin, but avoids much of the risk that some movement on the part of the patient under treatment may cause accidental burns.

FULTON'S BIBLIOGRAPHY OF ROBERT BOYLE

As R. T. Gunther pointed out in "Early Science on Oxford," medicine owes more than can be readily defined to Robert Boyle for his influence in establishing a proper physical and chemical basis for the study of the human body in health and disease. Though much in Oxford from 1654 to 1668 and a leading spirit in its Philosophical Society, he was never a "gown-man" there. But in 1665 he was created a Doctor of Physic, he endowed an annual lecture in defence of natural and revealed religion, and his name is further kept green by the Robert Boyle lecture, founded in 1892 by the Oxford University Junior Scientific Club. It is therefore fitting that at Oxford the University Press, under the guidance of her Biographical Society, should bring out the scholarly and fascinating "Bibliography of the Honourable Robert Boyle"[1] which, after collecting for eight years the early editions of these works, Dr. J. F. Fulton, sometime Fellow of Magdalen College, Oxford, and now Professor of Physiology at Yale, has compiled. It contains 250 items of Boyle's works, a section on works dedicated to him, including Joseph Needham's "The Sceptical Biologist" (1930), his funeral sermon and elegies, his biographies and the criticisms and commentaries made about him. The formal list of Boyle's publications and their various editions is generously illustrated by photographic facsimiles ie title pages, and is accompanied by explanatory extremely interesting descriptions. In an actively modest preface the difficulties inherent ompiling a seventeenth century scientific biblio- hy are confessed, and the method which the lern bibliographer must adopt to obtain a result satisfies his conscience and ideals is revealed to reader. As the author remarks, "bibliography is ed an all-absorbing occupation, but its devotee is uently face to face with those who fail to under- ld the source of his enjoyment." This fine work, the splendid "Bibliotheca Osleriana" (1929), t earn the sincere gratitude of those interested in bibliography of medical science to the Oxford versity Press.

NOTHER ACTIVE CONSTITUENT OF ERGOT

REMARKABLE paper by Dr. Chassar Moir,[1] from obstetric unit of University College Hospital, cludes with the statement that there is a reasonable tainty that the characteristic action of ergot known the old obstetricians is due to a substance which a prompt and energetic action, and which is not otoxine, ergotamine, tyramine, or histamine; t, in fact, the ergot alkaloids, hitherto supposed be all-important, play but a subsidiary part in the ical action of the drug. This is an astonishing ling to those who have followed the controversy arding the activity of the B.P. extracts of ergot.

Nearly a quarter of a century ago, G. Barger and H. Carr isolated from ergot an alkaloid which y called ergotoxine, and which was believed to be ponsible for the only characteristic pharmaco- ical action of the drug. Later on, histamine and amine were found in ergot, but it was soon monstrated that these amines had no effect on the erus when given by mouth. The view has since been ongly pressed by pharmacologists that the processes which the pharmacopœial extracts of ergot were ade might have been conceived with the definite ject of ensuring that these extracts should contain ne of the only active principle peculiar to, and aracteristic of, the drug; the inference being that e B.P. extracts were absolutely inert and therefore eless. Clinical opinion demurred to this conclusion. seemed almost unbelievable that the watery extracts ed by clinicians for over a century, and concerning e efficacy of which there seemed to be convincing inical proof, should be valueless. But the work of Bourne and J. H. Burn[2] on the human parturient erus appeared to confirm the views of the pharmaco- gists that ergotoxine and ergotamine (an alkaloid olated by Stoll in 1920, closely related to ergotoxine, ough probably not chemically identical) were lely responsible for the therapeutic efficacy of any eparation of ergot, and that the watery extracts ere inactive. This view came to be generally cepted, except perhaps by those who were actually the habit of employing ergot in their practice; nd in the new pharmacopœia, to be published ortly, methods of extraction with acid alcohol re substituted for the old watery extracts, so as to nsure the presence of what were regarded as the ctive alkaloids. Now the whole controversy has aken a new turn.

Moir employed a modification of Bourne and Burn's ethod to obtain records in graphic form of the ontractions of the puerperal uterus. About the eventh day of the puerperium, a sterilised rubber bag is passed into the uterus, and connected by water-filled tubing to a mercury manometer. By means of a light float on the manometer variations of intra-uterine pressure are recorded on a slowly revolving drum. In this way, not only the spontaneous contractions of the puerperal uterus are clearly shown, but also the variations of activity brought about by suckling or by the administration of drugs. Moir demonstrates that while both ergotoxine and ergotamine are active in stimulating contractions of the puerperal uterus, they are comparatively slow in taking effect, requiring 15 to 45 minutes after intra-muscular injection, and 35 to 40 minutes or longer when given by mouth. Furthermore, their action when given orally is erratic. On the other hand, the administration by mouth of different samples of the B.P. 1914 Ext. ergotæ liq. in 2-drachm doses and of the Ext. ergotæ in grs. 10 doses, results within a few minutes in marked activity of the puerperal uterus, the tone of which is also increased to an extent much greater than that seen with any other oxytocic drug. The rapid effect demonstrated in this way is in entire agreement with recorded clinical facts. Ergot could never have had a place in obstetrics had its action not been swift and powerful. It would appear also that these extracts have remarkable keeping properties, samples known to have been kept in a partly used stock bottle with a cork stopper for more than 15 months being still very active. It is difficult to resist the conclusion that the characteristic and traditional effect of ergot is due to a substance as yet unidentified, and that the clinicians who maintained that watery extracts of ergot were useful were entirely right. It should be a warning to the laboratory worker not to be too severe in his criticism of clinical observation, which might be as accurate as his own. Fortunately, by what may be described as a happy fluke, the alcoholic ergot extract of the new B.P. appears to be as active as the watery extract of the old B.P., when given by mouth.

ANÆSTHETICS AND THE MIDWIFE

THE demand among women of all classes that they shall know as little as possible of the pains of childbirth appears to be increasing, but at present the women whose labour is conducted in their own homes by midwives can expect little relief from pain even at the stage of actual delivery. The suggestion that small doses of chloroform should be put up in capsules and used for this purpose was made recently by Miss E. M. Pye,[1] president of the Midwives Institute. Each capsule contains ♏xx of chloroform and is enclosed in a roll of gauze; it can be crushed between the fingers so that the chloroform soaks into the gauze roll. One capsule tucked into the side of a mask is said to be sufficient to secure analgesia for 7 to 10 minutes. Mr. Rivett, who has given the capsules extensive trial both at Queen Charlotte's and the Middlesex Hospitals, allows their use early in the first stage of labour. The patient sniffs the mask whenever she feels a pain beginning, and a very small quantity of chloroform—"little more than the smell of it," in Mr. Rivett's experience—suffices to procure analgesia. No attempt is made to induce surgical anæsthesia; the patient remains conscious of the contractions, but these are painless. At a meeting of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine (reported on p. 1361), at which Mr. Rivett described the success obtained with the capsules, several

speakers suggested that the action of chloroform, used in such a way, was largely psychological. Mr. Eardley Holland is able to achieve a similar happy result during the first stage of labour by reassurance, persuasion, and grs. 40 of chloral; and he deprecates the prolonged use of chloroform, even in such small dosage. Most speakers, however, seemed to think the capsules harmless enough, though some feared to place a drug as dangerous as chloroform in the hands of the midwife. Dr. Fairbairn, president of the Central Midwives Board, expressed interest in the device, and the opinion of the Section of Anæsthetics of the Royal Society of Medicine is being enlisted on the question whether midwives, after preliminary training, could safely be trusted with the capsules.

ANOTHER CLINIC FOR THE "NERVOUS" CHILD

THE movement towards the rational treatment of the so-called "nervous" or difficult child has been gaining ground through the pioneer work of a variety of organisations throughout the country. In London alone we have one under the auspices of the Child Guidance Council of Great Britain, the East London Child Guidance Clinic of the Jewish Health Organisation, a special department at the Institute of Medical Psychology, and the National Institute of Child Psychology; while Guy's Hospital, the Children's Hospital, Great Ormond-street, University College Hospital, and Maudsley Hospital each have departments devoted to this work. The two first mentioned, and those in Birmingham and Liverpool, are planned on the American system of a clearly defined unit of psychiatrist, psychologist, and social worker who deal with the cases in close collaboration. The others are mostly equipped with the same basic staff, but the unit is closely organised and is related to the hospital to which each is attached. The West End Hospital for Nervous Diseases now proposes to establish a similar unit in the autumn, to which members of the hospital staff will be able to refer cases for special treatment, though cases will also be accepted from other sources. This will mean that not only will those "nervous" and difficult children be seen who have been diagnosed as free from organic disease, but that such organically afflicted children as have behaviour sequelæ will be considered for psychological assessment (intelligence estimation, and so forth), and perhaps for treatment too. Observation beds will be available. This venture is of interest in that, for the first time, a hospital for organic nervous diseases is considering the more psychological aspects of child disorders on modern lines.

Clinics that are not directly associated with hospitals tend to attract a large number of cases of the "behaviour" type, largely from the schools. The cases are chosen in consequence of the teachers' attitude and the demands of school life, its curriculum and its discipline. Such clinics may fail to attract the attention of medical practitioners, or may not win their confidence because of the fear of entanglements with new theories away from the beaten track of medical tradition. It is important that such fears should be dispelled, but this will be only a gradual process. Meanwhile, the advantage of the West End Hospital clinic may lie in the fact that most doctors have, through tradition, associated disorders of behaviour and emotion with the action of the nervous system in the widest sense, despite the fact that disturbances in other systems are not without their psychological implications. It is, moreover, an admission that while careful differential diagnosis of nervous disorder is the first requisite, treatment must follow on specific lines, psychological and perhaps sociological. The fact that London is now being rapidly provided with a variety of children's clinics, bearing a basic resemblance to each other in the recognition of the need for medical, psychological, and sociological investigation, is satisfactory; and since each is related to different hospitals and different forms of psychological or psychiatric organisation, their study of behaviour and emotional disorders in children will soon be approached from many fresh angles.

A GROWTH-PROMOTING FACTOR

IN a paper presented to the Biochemical Society on June 11th, Mr. L. W. Mapson, of Cambridge, stated[1] that fresh ox liver has been shown to contain a substance which stimulates the growth of rats, maintained on a full synthetic diet, to approximately twice the normal rate. This accelerative growth-response is relatively more marked in the male than in the female. It has been transmitted from parent to offspring by the feeding of liver to the parents, and the stimulation of growth is greater under these conditions than when the liver is fed directly to the young. This growth-promoting principle, according to Mapson's observations, is distinct from hitherto known accessory food factors. Preliminary investigations show that it is soluble in water and is not precipitated by high alcohol concentrations. Commercial liver extracts such as Eli Lilley No. 343 contain only traces of it. A beneficial effect of feeding fresh ox liver has also been noted in connexion with lactation; 30 per cent. only of the control animals succeeded in the rearing of their offspring, whereas no such failure of lactation occurred in those litters whose parents received liver in supplement to the basal diet. Evidence of some stimulation of ovarian activity by the feeding of liver is indicated by the readiness with which the animals breed and the increased numbers of young born in the liver-fed litters. Whether the substance active in promoting the growth rate is identical with that stimulating lactation remains to be determined, and a fuller account of the work is shortly to be published.

THE X Ray and Radium Protection Committee is making an inquiry into the blood changes which occur in workers in radiological departments. Sir Humphry Rolleston (chairman), and Prof. Sidney Russ and Dr. Stanley Melville (hon. secretaries) have issued to hospitals a questionnaire inviting information. Copies may be had from Dr. Melville at 9, Chandos-street, London, W.1.

IT is announced that Sir John Marnoch is retiring on Sept. 30th from the Regius chair of surgery in the University of Aberdeen.

Miss Ruth Darwin has been appointed a senior commissioner of the Board of Control, in succession to Mrs. Ellen F. Pinsent, who will retire on July 31st. Mrs. Pinsent was an honorary commissioner from 1913 to 1920 and a commissioner from 1921 to 1930; she has been a senior commissioner since Jan. 1st, 1931, when the Board was recognised under the Mental Treatment Act. Miss Darwin, who is a daughter of the late Sir Horace Darwin, was an honorary commissioner from 1920 to 1930, and has been a commissioner since 1931.

WHAT IS WRONG WITH THE MEDICAL CURRICULUM?

Series of Opinions Contributed by Request)

III

G. GREY TURNER, M.S., F.R.C.S., F.A.C.S.
FESSOR OF SURGERY IN THE UNIVERSITY OF DURHAM

is perhaps easy to criticise the medical
ulum from a general point of view, but more
lt to do so from the point of view of the subject
hich one has special responsibility. It is so
to say that the student spends far too much
in other departments, and so difficult to admit
his duties could be lightened in one's own
t. The time in the curriculum at which the
nt starts his clinical work is always a moot
, and I cannot personally see why he should
et some introduction to hospital life at a much
r period. To defend this thesis would lead one
spass on the domain of the anatomist and physio-
, but I venture to say that an unnecessary
nt of time is spent in the actual work of dissecting
n the study of the minutiæ of anatomy, and that
at deal of physiology could be much better
t on the living human subject than in the
exclusive atmosphere of the laboratory. Truly
erful "experiments" are carried out every day
e surgical wards and provide opportunities for
tudy of living processes on the human being.
could be easily observed if only this work
organised and it was someone's business, with
ledge and time, to direct its manifold lessons
the proper channel of the student's mind.
tless those in charge of hospital beds could utilise
of these opportunities and carry the student's
ledge of the Institutes of Medicine into the
al sphere; but there is always the unhappy
of these days, and in the surgical wards the
tant drain on the time and energy of the surgeon
he insistent claims of the operating theatres.

INITIATION

the outset I would like to utter a protest against
tudent's time-table being too much cut and dried
he first enters hospital with set classes and
onstrations which he must attend in order to be
d up. I have always thought that during the
three months of clinical study the student ought
e allowed to go anywhere and everywhere, and
ave the opportunity to wander around the strange
of a hospital, and to follow his own interests
whatever department they may lead. In this
he will take a peep at injury and disease from all
ts of view, and will learn to find his way about the
g body much as he learned to find his way about
dead body in the dissecting room. He will also see
h, and in the post-mortem room he can, even at
stage, roughly correlate the condition of the quick
the dead. During this formative period he
ld keep a note of what he sees, and should read
those particular things in the excellent text-books
ch are available, rather than attempt from the
inning to learn his work by a course of systematic
ling so many pages a day. It would be a good
g if, in these early days, he could hear something
the history of his art, not formal teaching but
enough to whet his appetite and to make him familiar with the great names. After that period has passed, the student may start his appointments and, so far as surgery is concerned, I would most emphatically say that the post of dresser is an admirable education, and that the period of dressership is none too long and need never be wasted. It is the nearest approach to an apprenticeship which is now feasible. During this time the student is not only being taught, but is learning to teach himself, and in the daily contact with the sick he gets an intimate introduction to what must be his life's work. He becomes inoculated with the hospital spirit, becomes part of a humanitarian machine, and helps to keep ajar the ever open door.

It is quite true that in after-life he may not be called upon to wash out bladders—and perhaps many of them—every day, or to perform many other things that those of a certain temperament look upon as entirely menial duties; but all the while he is learning the relationship between patient and attendant in a way which is most valuable. To learn to talk to patients; to handle patients; to be gentle and be commended for it, or to be rough and to hear disdainful remarks; this is valuable training, which should not be left out of a proper educational scheme. May I say that one factor in the medical curriculum is constantly overlooked, and that is the amount of learning that is imparted by the hospital nursing staff, especially the experienced sisters, during the time the student is holding appointments.

THE PLACE OF LECTURES

Much has been said in criticism of systematic lectures, and it is frequently stated that they are of little or no value now that such excellent text-books are available, but one would like to hear what students themselves say about this part of the curriculum. I feel that I know the answer, and that it would turn out that there are two principal groups—those who learn from lectures and those who cannot; but I fancy that if the lectures were of the proper sort the first class would preponderate. In my school the surgical lectures have been diminished to what is considered a reasonable number, and for three terms the students must attend didactic lectures three times a week. The first term, comprising 25 lectures, deals with the principles of surgery—the rules of the game, the foundations of the art; and this part of the course ought to be valuable. It is impossible for instance in any course of surgery of reasonable length to deal with *hæmorrhage* under every conceivable circumstance, but it is comparatively easy to lay down rules which should govern the treatment of hæmorrhage wherever it occurs, and to indicate, by reference to certain clinical illustrations, how these rules can be applied. The same holds good for a subject like *fractures*, for there the multiplicity of methods which in any one school the student may see carried out for identical fractures must be confusing. In lectures it ought to be possible to lay down and illustrate the principles involved in such a way that the student can recognise that in the various methods employed there need be no violation of these general principles, although the same ends are obtained by such very different means.

In the second two terms the lectures are devoted to regional surgery, and in this course the lecturer does not endeavour to cover the whole of the regions of the body, but enlarges upon the more common

speakers suggested that the action of chloroform, used in such a way, was largely psychological. Mr. Eardley Holland is able to achieve a similar happy result during the first stage of labour by reassurance, persuasion, and grs. 40 of chloral; and he deprecates the prolonged use of chloroform, even in such small dosage. Most speakers, however, seemed to think the capsules harmless enough, though some feared to place a drug as dangerous as chloroform in the hands of the midwife. Dr. Fairbairn, president of the Central Midwives Board, expressed interest in the device, and the opinion of the Section of Anæsthetics of the Royal Society of Medicine is being enlisted on the question whether midwives, after preliminary training, could safely be trusted with the capsules.

ANOTHER CLINIC FOR THE "NERVOUS" CHILD

THE movement towards the rational treatment of the so-called "nervous" or difficult child has been gaining ground through the pioneer work of a variety of organisations throughout the country. In London alone we have one under the auspices of the Child Guidance Council of Great Britain, the East London Child Guidance Clinic of the Jewish Health Organisation, a special department at the Institute of Medical Psychology, and the National Institute of Child Psychology; while Guy's Hospital, the Children's Hospital, Great Ormond-street, University College Hospital, and Maudsley Hospital each have departments devoted to this work. The two first mentioned, and those in Birmingham and Liverpool, are planned on the American system of a clearly defined unit of psychiatrist, psychologist, and social worker who deal with the cases in close collaboration. The others are mostly equipped with the same basic staff, but the unit is closely organised and is related to the hospital to which each is attached. The West End Hospital for Nervous Diseases now proposes to establish a similar unit in the autumn, to which members of the hospital staff will be able to refer cases for special treatment, though cases will also be accepted from other sources. During this formative period he ould keep a note of what he sees, and should read those particular things in the excellent text-books ich are available, rather than attempt from the ginning to learn his work by a course of systematic ading so many pages a day. It would be a good ing if, in these early days, he could hear something the history of his art, not formal teaching but enough to whet his appetite and to make him familiar with the great names. After that period has passed, the student may start his appointments and, so far as surgery is concerned, I would most emphatically say that the post of dresser is an admirable education, and that the period of dressership is none too long and need never be wasted. It is the nearest approach to an apprenticeship which is now feasible. During this time the student is not only being taught, but is learning to teach himself, and in the daily contact with the sick he gets an intimate introduction to what must be his life's work. He becomes inoculated with the hospital spirit, becomes part of a humanitarian machine, and helps to keep ajar the ever open door.

It is quite true that in after-life he may not be called upon to wash out bladders—and perhaps many of them—every day, or to perform many other things that those of a certain temperament look upon as entirely menial duties: but all the while he is learning the relationship between patient and attendant in a way which is most valuable. To learn to talk to patients: to handle patients: to be gentle and be commended for it, or to be rough and to hear disdainful remarks; this is valuable training, which should not be left out of a proper educational scheme. May I say that one factor in the medical curriculum is constantly overlooked, and that is the amount of learning that is imparted by the hospital nursing staff, especially the experienced sisters, during the time the student is holding appointments.

THE PLACE OF LECTURES

Much has been said in criticism of systematic lectures, and it is frequently stated that they are of little or no value now that such excellent text-books are available, but one would like to hear what students themselves say about this part of the curriculum. I feel that I know the answer, and that it would turn out that there are two principal groups—those who learn from lectures and those who cannot: but I fancy that if the lectures were of the proper sort the first class would preponderate. In my school the surgical lectures have been diminished to what is considered a reasonable number, and for three terms the students must attend didactic lectures three times a week. The first term, comprising 25 lectures, deals with the principles of surgery—the rules of the game, the foundations of the art: and this part of the course ought to be valuable. It is impossible for instance in any course of surgery of reasonable length to deal with *hæmorrhage* under every conceivable circumstance, but it is comparatively easy to lay down rules which should govern the treatment of hæmorrhage wherever it occurs, and to indicate, by reference to certain clinical illustrations, how these rules can be applied. The same holds good for a subject like *fractures*, for there the multiplicity of methods which in any one school the student may see carried out for identical fractures must be confusing. In lectures it ought to be possible to lay down and illustrate the principles involved in such a way that the student can recognise that in the various methods employed there need be no violation of these general principles, although the same ends are obtained by such very different means.

In the second two terms the lectures are devoted to regional surgery, and in this course the lecturer does not endeavour to cover the whole of the regions of the body, but enlarges upon the more common

speakers suggested that the action of chloroform, used in such a way, was largely psychological. Mr. Eardley Holland is able to achieve a similar happy result during the first stage of labour by reassurance, persuasion, and grs. 40 of chloral; and he deprecates the prolonged use of chloroform, even in such small dosage. Most speakers, however, seemed to think the capsules harmless enough, though some feared to place a drug as dangerous as chloroform in the hands of the midwife. Dr. Fairbairn, president of the Central Midwives Board, expressed interest in the device, and the opinion of the Section of Anæsthetics of the Royal Society of Medicine is being enlisted on the question whether midwives, after preliminary training, could safely be trusted with the capsules.

ANOTHER CLINIC FOR THE "NERVOUS" CHILD

THE movement towards the rational treatment of the so-called "nervous" or difficult child has been gaining ground through the pioneer work of a variety of organisations throughout the country. In London alone we have one under the auspices of the Child Guidance Council of Great Britain, the East London Child Guidance Clinic of the Jewish Health Organisation, a special department at the Institute of Medical Psychology, and the National Institute of Child Psychology; while Guy's Hospital, the Children's Hospital, Great Ormond-street, University College Hospital, and Maudsley Hospital each have departments devoted to this work. The two first mentioned, and those in Birmingham and Liverpool, are planned on the American system of a clearly defined unit of psychiatrist, psychologist, and social worker who deal with the cases in close collaboration. The others are mostly equipped with the same basic staff, but the unit is closely organised and is related to the hospital to which each is attached. The West End Hospital for Nervous Diseases now proposes to establish a similar unit in the autumn, to which members of the hospital staff will be able to refer cases for special treatment, though cases will also be accepted from other sources. This will mean that not only will those "nervous" and difficult children be seen who have been diagnosed as free from organic disease, but that such organically afflicted children as have behaviour sequelæ will be considered for psychological assessment (intelligence estimation, and so forth), and perhaps for treatment too. Observation beds will be available. This venture is of interest in that, for the first time, a hospital for organic nervous diseases is considering the more psychological aspects of child disorders on modern lines.

Clinics that are not directly associated with hospitals tend to attract a large number of cases of the "behaviour" type, largely from the schools. The cases are chosen in consequence of the teachers' attitude and the demands of school life, its curriculum and its discipline. Such clinics may fail to attract the attention of medical practitioners, or may not win their confidence because of the fear of entanglements with new theories away from the beaten track of medical tradition. It is important that such fears should be dispelled, but this will be only a gradual process. Meanwhile, the advantage of the West End Hospital clinic may lie in the fact that most doctors have, through tradition, associated disorders of behaviour and emotion with the action of the nervous system in the widest sense, despite the fact that disturbances in other systems are not without their psychological implications. It is, moreover, an admission that while careful differential diagnosis of nervous disorder is the first requisite, treatment must follow on specific lines, psychological and perhaps sociological. The fact that London is now being rapidly provided with a variety of children's clinics, bearing a basic resemblance to each other in the recognition of the need for medical, psychological, and sociological investigation, is satisfactory; and since each is related to different hospitals and different forms of psychological or psychiatric organisation, their study of behaviour and emotional disorders in children will soon be approached from many fresh angles.

A GROWTH-PROMOTING FACTOR

IN a paper presented to the Biochemical Society on June 11th, Mr. L. W. Mapson, of Cambridge, stated[1] that fresh ox liver has been shown to contain a substance which stimulates the growth of rats, maintained on a full synthetic diet, to approximately twice the normal rate. This accelerative growth-response is relatively more marked in the male than in the female. It has been transmitted from parent to offspring by the feeding of liver to the parents, and the stimulation of growth is greater under these conditions than when the liver is fed directly to the young. This growth-promoting principle, according to Mapson's observations, is distinct from hitherto known accessory food factors. Preliminary investigations show that it is soluble in water and is not precipitated by high alcohol concentrations. Commercial liver extracts such as Eli Lilley No. 343 contain only traces of it. A beneficial effect of feeding fresh ox liver has also been noted in connexion with lactation; 30 per cent. only of the control animals succeeded in the rearing of their offspring, whereas no such failure of lactation occurred in those litters whose parents received liver in supplement to the basal diet. Evidence of some stimulation of ovarian activity by the feeding of liver is indicated by the readiness with which the animals breed and the increased numbers of young born in the liver-fed litters. Whether the substance active in promoting the growth rate is identical with that stimulating lactation remains to be determined, and a fuller account of the work is shortly to be published.

THE X Ray and Radium Protection Committee is making an inquiry into the blood changes which occur in workers in radiological departments. Sir Humphry Rolleston (chairman), and Prof. Sidney Russ and Dr. Stanley Melville (hon. secretaries) have issued to hospitals a questionnaire inviting information. Copies may be had from Dr. Melville at 9, Chandos-street, London, W.1.

IT is announced that Sir John Marnoch is retiring on Sept. 30th from the Regius chair of surgery in the University of Aberdeen.

Miss Ruth Darwin has been appointed a senior commissioner of the Board of Control, in succession to Mrs. Ellen F. Pinsent, who will retire on July 31st. Mrs. Pinsent was an honorary commissioner from 1913 to 1920 and a commissioner from 1921 to 1930; she has been a senior commissioner since Jan. 1st, 1931, when the Board was recognised under the Mental Treatment Act. Miss Darwin, who is a daughter of the late Sir Horace Darwin, was an honorary commissioner from 1920 to 1930, and has been a commissioner since 1931.

MEDICINE AND THE LAW

A Surgeon's Authority to Operate

In the High Court last week Mrs. Cull brought action against the Royal Surrey County Hospital, ildford, and Mr. H. B. Butler, the surgeon in rge of its gynæcological department. She alleged gligence, breach of contract, and trespass to the son.

Mrs. Cull suffered from epileptic fits. According her evidence she was now 32 years old. one of a ily of eight children all alive and healthy, her rents being also alive and healthy. At 14 years age she had a fit which she attributed to a paper g being burst on her head. Thenceforward she d epileptic fits at intervals of from 12 to 18 months. e married at 20, and had a child, now aged 11 years, lthy and strong. A second child was born in 22. but died of pneumonia at 10 months. Her bsequent medical history appears from the evidence Dr. Gordon Cranstoun, of Worplesdon, her medical endant. He first attended her during a pregnancy 1928; she was then suffering badly from fits, ich became worse towards the end of her time: e child was born dead. In 1929 she and her husnd consulted Dr. Cranstoun as to the advisability any future pregnancy. He advised against it; egnancy caused her epileptic condition to become rse. In October, 1929. she was again pregnant. e told him her health was worse and her fits were d, and hoped the pregnancy could be terminated. e suggested a consultation with Mr. Butler, who vised removal of the uterus. Dr. Cranstoun plained the position to Mr. and Mrs. Cull. Later . Cull told him they had decided against the ajor operation. and preferred the minor operation curetting. because Mr. Cull had to go away to the ld Coast on duty, and could not leave his wife to dergo the major operation in his absence. Dr. anstoun replied that, if the pregnancy were thus minated, it could not be regarded as a matter of nvenience; there must be no more pregnancies. . Cull assured him that there should be no future gnancy.

The patient was admitted to the Royal Surrey unty Hospital. and Dr. Cranstoun wrote a letter the hospital conveying her decision not to undergo e major operation. Though this communication ached the hospital it was never brought to the geon's notice; it was attached to the "in-patient's ter" referring to Mrs. Cull and was filed. In the mission book the words "for curettage" were tered under the heading "Disease." The admisn form, destroyed in the ordinary routine. had parently specified "need for uterine curettage." the operation Mr. Butler removed the uterus. terwards, said Dr. Cranstoun, Mrs. Cull did not otest about what had been done, nor did she press regret or annoyance. It was put to him in s-examination that the fits had since become rse, but he declined to attribute this to the operan. Epilepsy, he said, is a progressive disease. d. moreover, the strain of the present litigation uld have a bad effect on the patient.

If Dr. Cranstoun's evidence were accepted—and seems to have been in no way shaken by crossamination or otherwise—the merits and substance Mrs. Cull's claim were obviously diminished. ere had been references to the desire of Mr. and s. Cull to have another child. and to the disaster Mrs. Cull's disability; if her husband had already undertaken, under medical advice, that there should be no future pregnancy, these references lost their forensic value. Mr. Butler, who was described by the Lord Chief Justice as a frank and candid witness. described his first examination of Mrs. Cull; he said he gathered she was terrified by the experience of her former pregnancies. and dreaded the continuance of the existing one; he came to the conclusion that the pregnancy ought to be removed and the patient sterilised. He agreed that the admission form bore the words "need for curettage"; he thought this must be a mistake; he could not imagine that, if there had been any disagreement with his advice. it would be conveyed by writing "need for curettage" on an admission form; he would have expected some proper means of indicating it. As he now knew, there was a proper document to this effect. but he never got the document. He himself went through the details of the case with the sister at the bedside, "including Mrs. Cull, as it were, in the conversation"; he did not remember Mrs. Cull making any remark. He admitted he was wrong in being satisfied, but these circumstances did satisfy him that the patient knew what he was going to do. He honestly believed Mrs. Cull was better off now; she was a woman who ought not to have another pregnancy. Further evidence was given for the defence by various witnesses. Mr. G. H. Steele, of Guildford, consulting surgeon to the hospital. said it would not have been proper to terminate Mrs. Cull's pregnancy in 1929 if there had been a prospect of a future pregnancy. Sir Henry Simson said that from the medical and eugenical point of view the patient certainly should not have had any more children: further pregnancies would have been a source of danger to her life and health; it was probable she would never have a healthy child. He had never heard it said that removal of the uterus made epilepsy worse; on the contrary, the operation had been recommended as a cure for epilepsy. Sir Farquhar Buzzard giving similar evidence said that the patient's medical history showed that she suffered from major epilepsy, and that pregnancy increased the epileptic condition; that tendency would be progressive. In his opinion the operation performed by Mr. Butler could not permanently affect the epilepsy. Sir Farquhar deprecated the marriage of epileptics; the only case in which an epileptic should marry was where, under treatment, there had been years of immunity.

In answer to specific questions left to them by the Lord Chief Justice, the jury found that there had been a negligent breach of contract by the hospital authorities. damages being assessed at £120. There had been trespass on the part of Mr. Butler, damages being assessed at the apparently contemptuous figure of one farthing. The jury added a rider that Mr. Butler's trespass was due to the hospital authorities' negligence. As £25 had been paid into court on behalf of Mr. Butler. the plaintiffs would ordinarily have to pay his costs. Lord Hewart has deferred his decision on the question of costs.

Spiritualism as a Subject of Libel

The legal requirement that an English jury should be unanimous must often encourage jurymen to compromise. The verdict in Mrs. Meurig Morris's action against the *Daily Mail* was possibly an instance of this tendency. Under the headline "Trance Medium found out," the defendant newspaper commented on Mrs. Morris's spiritualistic powers. When she sued for damages for libel. the defendants conditions which are of the greatest importance, and on conditions which, though important when they arise, are not so likely to be met with in the ordinary practice of the hospital during the comparatively brief period which the student spends in a medical school. These lectures, if given by someone with ample clinical experience, are really systematic surgery illustrated by reference to cases. I have never forgotten many valuable lessons conveyed in this way by my own teachers, and especially when in the form of a story around the history of an actual case.

Great stress should be laid on the ordinary methods of examination and in every case these should come first. I like to picture my students immured on some distant island, away from all institutions and modern apparatus, and to think that they at least by their training will be equipped to find out all that can be elucidated by the methods which have stood the test of time for so long. It is a good plan to educate the students to think of the ordinary things first, and gradually to work up to the more detailed and special examinations which may so often be required. Years ago I was horrified when a candidate in the final informed me that she had never made a rectal examination. This seemed to be so appalling a state of affairs that I now supply the students with a card on which is printed a list of all the ordinary minor procedures which they ought to have personally conducted. This is not for signing up purposes, but as a reminder to them of what they must see and do before they can consider that they have made full use of the abundant opportunities which are provided.

SURGICAL TECHNIQUE

In operative surgery my views are very decided, and I cannot but think that they must merit more or less general approval. It is quite impossible, even if it were thought desirable, to turn out ordinary graduates fully equipped to practise operative surgery in all its branches. But I feel that every student should have a clear grasp of surgical technique, both in all its broad principles and its essential details, and for a proper understanding of this important matter the story of Lister and his achievement is most helpful. They must also be well grounded in minor surgery, and in the great surgical emergencies which under any and varied circumstances may requiring life-saving operations. So far as the other methods of operative treatment are concerned, it is in my opinion quite unnecessary for the student to be burdened with any technical details whatever. I mind not at all whether they know the steps of gastrectomy, or of excision of the rectum, or division of the sensory root of the Gasserian ganglion, or the very many other major operations which ought only to be attempted by those who have undergone very special training, which must be post-graduate. But all who would qualify to practise should have a knowledge of the possibilities of operative treatment and some understanding of the indications for most surgical procedures. They should know something of the risks and of the results which may reasonably be expected, and incidentally they will learn, during their dressership, a good deal about the conduct of the after-treatment. Large numbers of our graduates will certainly take service under the panel system, and under that system the majority of minor surgical operations are supposed to be within the competence of any qualified medical man. That being so, it is part of their business to be equipped with knowledge of these minor procedures, or they are unfitted for the work which many of them contract to undertake.

TEACHING CENTRED ON THE PATIENT

I regret the wasted opportunities for teaching minor surgery which daily occur in all hospitals and I constantly tell my class that, so far as minor surgery is concerned, they may get very great credit from the successful conduct of some operation which in hospital may be looked upon as so trivial as to be beneath their notice. Again, I am frankly afraid of the tendency in modern teaching to rely on seemingly easy routes to learning, demonstrations that are much too dramatic, cinema shows, and even some lantern demonstrations, in which the student has only got to keep awake and to sit and look, but in which he takes no part. I know the temptation for I employ these methods, but they should only be used sparingly and mostly for senior students and post-graduates. With the abundant clinical materia which is available in most hospitals in this country it seems wicked to spend any time in teaching which is not centred around an actual patient. It is al very well to be able to demonstrate unusual conditions by graphic pictorial methods, but such demonstrations should surely be infrequent when there is so much that is ordinary that can be demonstrated at first hand. For this reason I think that clinica lectures should concern actual cases and, as far as possible, should be conducted around the patient I would also lay great stress on continuity in teaching and, as far as is possible, the student should see the case in the out-patient department, admitted to the wards, investigated, operated upon and sent out cured or otherwise, and any pathological specimens from the patient should be demonstrated to the students concerned. I suggest that a considerable amount of the student's time could be saved if it were not necessary to devote such close attention to pathological histology. Naked-eye pathology is of the greatest importance and on the surgical side canno be too much stressed, but nothing is so good as the study of specimens in connexion with the particular case to which they are related. Though a certain amount of pathological histology is essential, in actua practice in all but the simplest cases problems o microscopic diagnosis are nowadays submitted to those who specialise in this work, and no amount o training during the undergraduate period would make it possible for the young practitioner to be able to rely on his own opinion rather than that of experts in cases of difficulty. It is indeed entirely different with gross pathology, for under many circumstances the practitioner must be competent to recognise the nature of some pathological condition to enable him to act, though the confirmation may perhaps come at another time.

EPITOME

As the result of the only too brief time which the student spends in the study of surgery, he should not only be absolutely familiar with the details of everyday things, but should be so grounded in principles that in unusual difficulties they will serve as a general guide to action. In addition he should have the outlook of the perpetual student so that in any field he will know how to set about in search of new knowledge.

ROYAL EAST SUSSEX HOSPITAL.—The governors agreed, on June 17th, to purchase the university school and grounds, which adjoin this hospital, for £11,000. Extensive alterations will be necessary, but by the purchase of the freehold many thousands of pounds will be saved in not having to erect an entirely new building. The extension will increase the bed accommodation to 145, and leave room for more beds in emergencies.

reopen the door to corruption, and would prevent the development of confidence in the appointment of the officers of local authorities. Nothing could be said in its favour as regards professional officers at any rate.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

THE AMERICAN MEDICAL ASSOCIATION

THE American Medical Association met this year, for the fourth time in its history, at New Orleans. The serious economic condition of the country was reflected in the attendance; not more than 2778 physicians registered, fewer than were present at the last New Orleans gathering in 1920. Two States were without a single representative. The gravity of the present hour was also reflected in the opening address of its speaker, Dr. F. C. Warnshuis, to the House of Delegates on May 9th. "We are at present," he said, "in the vortex of readjustment along every avenue of human endeavour. New professional and public relationships are being formulated. On you ... rests the tremendous responsibility of . . . formulating the fundamental principles that will bring about acceptable readjustments wherein all the traditions and achievements of the medical profession will be conserved, and its relationship to patient and public enhanced." The relationship of the profession to society was also the main theme of the address of the president, Dr. E. Starr Judd, of Rochester, Minnesota. The address was conservative and yet took account of the reality of medico-economic problems and of the trend towards preventive medicine. "Organised medicine must do everything possible to escape having this function of the medical profession taken over exclusively by the Government."

At the third meeting of the House of Delegates a report was adopted asking the board of trustees to appoint a permanent committee to consider medical economy and the cost of medical care in European countries as well as at home. The subject of birth control was shelved. It was felt to be so controversial a subject that it was inadvisable even to appoint a committee to study the question. A resolution was carried protesting against the proposed reduction of the number of medical officers in the Army. For election as president-elect three names were put in nomination: Dr. Dean Lewis, professor of surgery in the Johns Hopkins medical school, Dr. Hugh Cumming, of Washington, and Dr. Fred Moore, of Iowa. Dr. Lewis was elected and Milwaukee was selected as the meeting place for 1933.

LABORATORY SERVICE BY MAIL

The most recent catalogue of Montgomery Ward and Co., which is one of the largest mail order concerns in the United States, contains an announcement of "A New Professional Service." The notice continues, "medical authorities agree that an analysis of the urine, even though the person does not feel ill at the time, often reveals sure signs of disease preparing to strike," and so on. A complete urine analysis "covering 29 chemical and microscopic tests" is offered for $1.50. The American Medical Association sent three specimens for examination, and the reports received were not very creditable. As a result the company have made an investigation themselves and now announce that they have discontinued this service.

THE SERVICES

I.M.S. ANNUAL DINNER

THERE was a large attendance of officers at the annual London dinner of the Indian Medical Service held at the Trocadero Restaurant on June 15th, to meet Sir Samuel Hoare, Secretary of State for India, who was the guest of honour. Importance was added to the occasion by the presence in the chair of Major-General J. W. D. Megaw, Director-General of the Service in India, who is on leave in this country. Nine officers on probation at the R.A.M. College, Millbank, were also there as guests.

Major-General MEGAW, proposing in a combined toast the health of the Service and the health of the Guests, began by conveying to the gathering a message of cordial greeting signed by General Graham from the officers of the I.M.S. now serving in India. He spoke of the rising stock of the Service when a slump might have been expected. They were getting excellent recruits; the last batch, he said, carried off all the prizes open to them at Millbank—a good omen for the future. Excellent relations continued between European and Indian members of the Service, in spite of the suggestion of some Indian politicians that the European members strove to maintain a medical monopoly in India. While it was creditable to all that the Indianisation of the Service had progressed so smoothly hitherto, it would be dangerous to force it unduly. He was glad to remind his fellow officers of the cordial relations existing with the R.A.M.C., paying a tribute to Major-General Nickerson, V.C., "who," he said, "had secured the love and esteem of the members of the I.M.S. as if he were a member himself." He congratulated members whose services had received public recognition during the year, among them Sir Leonard Rogers, Sir Richard Needham, General Graham, and Colonel Mackie, adding a word of sympathy to Sir Ronald Ross in his illness.

WHAT IS AT STAKE

Something more important, continued General Megaw, even than the preservation of the I.M.S. was at stake. There was no hope for India unless it had an efficient medical and public health organisation. That was a sweeping statement, but he made it with a full sense of responsibility. Let them consider the nature of the problem: a population of over 300,000,000, and rapidly increasing, engaged in a constant struggle for a precarious subsistence. Their task was to give these teeming millions a chance of securing a fair, rational, and satisfactory existence. None of the proposals of party politicians in India could influence to any appreciable extent the great elemental forces now ruthlessly at work. The problem of India was essentially biological, not political. He claimed that the medical research worker's first duty was to make a clear statement of the real nature of the problem and of the proper method of providing a solution. Medical and public health workers could not, of course, deal with the situation alone; they needed the coöperation of experts in agriculture, industry, economics, and education. It was clear to all unprejudiced observers that India was rapidly reaching a condition which would demand the united efforts of Indians and Europeans to deal with. When that time came it would be a matter of vital importance to India to have a supply of men of the kind that could only be provided by a strong All-India medical service. Every member of the I.M.S. had, he said, been greatly encouraged by the promise that the British Government was going to keep in the letter and in the spirit the contracts made with all the Indian services. There were signs of a desire to throw up the sponge pleaded justification and fair comment on a matter of public interest. The jury, after listening for 11 days, said no allegations of fraud or dishonesty against Mrs. Morris had been proved, but the article was fair comment on a matter of public interest. Mr. Justice McCardie construed this as a verdict for the defendants and gave judgment accordingly. Mrs. Morris naturally appealed. It seemed odd, as Lord Justice Scrutton remarked, that a newspaper could make a very defamatory charge against her and fail to prove it and yet not have to pay damages. Counsel for the newspaper argued that justification and fair comment were two different defences; if the first failed, the second might still succeed. It was possible that the jury, without coming to the conclusion that Mrs. Morris was a fraud, might still think that some of her claims were questionable and that on this ground the article might be justified. These arguments succeeded and Mrs. Morris lost her appeal. It is true that one of the ingredients of the defence of fair comment is that comment should be fair on facts accurately stated. Still the Court of Appeal decided that it was open to the jury to negative the charge of fraud and yet to say that they did not accept the view that the words complained of involved a charge of dishonesty. There was some evidence on which the jury could base its twofold verdict. It is a verdict which newspapers are likely to find useful.

A striking feature of Lord Justice Scrutton's judgment in the Court of Appeal is his reluctance to leave matters of faith to be tried on evidence before a jury. The Court was evidently disgusted by certain incidents which occurred at the trial. Mrs. Morris, said the Lord Justice, was a trance medium who made a series of statements which some people alleged to be the statements of dead persons speaking through the living; other people said these were mere manifestations of hysteria, having no connexion with any dead persons. This was an issue wholly independent of any question of fraud. Like some other issues, it could not be determined by evidence whether the voice was or was not the voice of a dead person. In Lord Justice Scrutton's view the idea of trying on evidence before a jury such questions as whether there was a Deity or whether there was a hell in another world was one from which sensible persons would recoil. "Such questions are for the faith of each individual citizen on such evidence as he thinks convinces him that he may have faith." A later passage in the Lord Justice's observations seemed to leave little doubt as to his own personal views of Mrs. Morris's trance revelations. It was, he said, rather a mixed committee of dead people who communicated through the plaintiff. There was a dead Indian squaw and a child of 6; if they were alive, no great importance would attach to their communications. Then there was a dead Irish priest who prefaced what he wished to say with "Begorra" and "Sure." There was also a person who declined to say who he was but who had been labelled "Power." These and other references in the Court of Appeal will hardly gratify Mrs. Morris and her supporters, but she has at least the satisfaction that nothing can deprive her of the jury's rejection of the accusation of fraud and dishonesty.

THE METROPOLITAN HOSPITAL.—This institution in the Kingsland-road is faced with a serious financial crisis; tradesmen's bills are outstanding to a considerable amount, the hospital being already in debt and heavily mortgaged. A meeting is being held to consider the position.

IRELAND

(FROM OUR OWN CORRESPONDENT)

NATIONAL HEALTH INSURANCE IN THE FREE STAT

THE Minister for Local Government and Publi Health made a serious statement to representative of the approved societies last week. He told ther *that the financial basis of the national health* insuranc scheme was no longer secure, and that the schem must undergo a thorough revision in the immediat future. The announcement has an unfortunat importance for medical men. The medical professio has long expected a system of medical treatment fo insured persons, and it was known that the lat Minister for Local Government and Public Healt was sympathetic with such a development, but wa withheld from action from lack of funds. Th announcement made last week means not only tha there will be no progress of national health insuranc for the present, but that there will be a retrogressiv move. It is even possible that the existing provisio of funds to pay for medical certificates of incapacit for work may be endangered. The amount, althoug important to medical men, is a trivial item in nationa health insurance expenditure.

IRISH MEDICAL ASSOCIATION

The annual meeting of the Irish Medical Associatio was held in Dublin on June 8th, when Dr. Robert J Rowlette was elected President, and Dr. J. T. Dani was re-elected Vice-President. The Presiden delivered an address on the Need for Organisation the Medical Profession in Ireland. He referred to th *history of the association*, which was now enterin on its ninety-fourth year. He sketched the histor of reforms in the poor-law medical service which ha been brought about mainly by the pressure professional organisations. The association had als exerted itself in promoting the establishment a public health service. In the constitution of th association the public welfare took precedence of th interests of the medical profession. The work reform had been shared for many years, bu particularly in recent years, by the British Medic Association. To the Irish Medical Committee wa due the credit of safeguarding the interests of th profession when they were threatened by the Nation Health Insurance Acts. The President commente on the lack of interest in organisation shown by th medical profession of to-day. Hardly more than on fourth of the practitioners in the Irish Free Stat were members of any organisation. He did no think the position at all a safe one, and he referred certain dangers which threatened professional an public interests at the moment. Medical men in th Government service had been warned that thei salaries were to be "cut" in percentages which woul in some cases be as great as 12½ per cent. Such a interference with contracted salaries, besides being grave hardship to the officers affected, would d away with the sense of security which was, up to th present, one of the chief inducements to professiona men to enter the public service, and would tend t deter the best class of candidates in the futur It had been stated too, apparently with authority that it was intended to alter the method of workin of the Local Appointments Commission which ha proved very successful in the last six years, in such way as to reintroduce local influence in the appoint ment of professional as well as lay officers of loca authorities. Such an alteration of method woul

PANEL AND CONTRACT PRACTICE

Emergency Help for ex-Service Men

THE Joint Council of the Order of St. John and the itish Red Cross Society has an emergency fund igned to give immediate help in emergencies for abled ex-Service men or their widows, and the mmittee are in some doubt whether the possibilities this fund are sufficiently realised by those who may e in contact with cases of distress to which it might applied. The need must be connected with the ablement or death of an ex-Service man, not an icer; the man must have had good effective vice during the Great War, and the proposed istance must not be primarily within the scope of me other voluntary fund or of a public authority. oreover, there must be some definite end in view; e fund is not able to grant anything in the nature a pension to a man whose income is chronically ufficient. The more usual forms of assistance are intenance of a man suffering from a temporary eakdown due to his pensional disability; the ovision of a period of convalescence; assistance men and widows who are awaiting a decision from e Ministry of Pensions; grants for some definite ject like special diet, dental treatment, surgical pliances, bed and bedding, removal expenses or ols; and business grants or loans to men and their idows. The regulations are very elastic, and special nsideration is given to any case which does not come rictly within the limits laid down. There are ergency help representatives in all parts of the untry who will gladly give advice and assistance d. if the case is not suitable for this particular fund, ill do all they can to find the correct source of sistance and to give help during the transfer if there urgent need. The central address of the fund is: oint Council House, 12, Grosvenor-crescent, London, W.1. The committee feels that insurance doctors e likely to come in contact with suitable cases, and anxious that all medical men employed in such ork should be aware of the facilities available.

Public Medical Services

There are in existence in many parts of England hemes for the provision of general practitioner eatment to persons with an income below about 250 per year. One of the oldest of these is active Leicestershire; the Essex Public Medical Service as just presented its eighth annual report, and the ondon Public Medical Service (started in 1926) one of the younger schemes—the object of all ese schemes being to provide an adequate service patients who cannot afford private fees. It is mewhat surprising that in these hard times scarcely y public authorities have taken advantage of them, eferring, it seems, to employ one or more wholeme practitioners in a special building rather than ractitioners of these services in their own surgeries. or the income limit of £250 probably the highest eekly fee is 4*d*. per person, and even this rate is odified where there is a family of dependant children. These schemes are carried on by a committee of octors elected by the doctors working the service. ree choice of doctor is provided, and in contrast ith the present panel regulations, patients, if disatisfied with the doctor of their choice, can change another without waiting.

In London the baby clinic welfare surgery has been ound popular with subscribers. The doctor working the service usually sets apart one convenient time his week in which he does nothing but give advice on infant welfare, issuing printed instructions to mothers, with modifications where necessary, for the feeding of babies at various stages. The mothers appreciate advice from the doctor who attended them in confinement and are certain to stick to their own doctor, provided they feel he is interested and competent, and that there is no extra cost. In contradistinction the usual welfare clinic run by the local authority is staffed by doctors whose knowledge of home conditions may be slight, and who have no further responsibility for the babies and mothers after the consultation at the clinic is over. But the mother does not get patent foods at cost price from the practitioner.

Before these medical service schemes came into existence there certainly was an argument that poor people could not afford to see their own doctor, but that excuse—except in the case of the destitute—does not now exist. Some few public authorities do use a public medical service for the working of their infant welfare clinic, and even for public assistance work. Much economy would result from an extension of this practice. The same principle applies to hospitals where it has been recently stated nearly 70 per cent. of out-patients attend without introduction from their own doctor. The time of the hospital consultant is thus wasted by persons able to obtain adequate general practitioner treatment at home, either privately or under some public medical service scheme, as well as by others who have been the round of many hospitals, and some who probably are at the moment under the doctor of their own choice, and are not in need of special treatment.

ESSEX PUBLIC MEDICAL SERVICE

Dr. A. P. Eldred presided, in the absence of the chairman, Dr. C. H. Panting, at the eighth annual meeting of this service, held at the Liverpool-street Hotel, London, on June 9th. During the past year there has been an improvement in all directions in spite of the widespread depression in trade. Apparently, the service is one of the last items of expenditure with which a family dispenses. The total number of subscribers on the books at the end of 1931, after deducting cancellations, removals, deaths, &c., was 19,477—an increase over the previous year of 914. Of this increase the gain in the number of adults was much greater than that in children. For the first two years of the service's existence there were seven children to every five adults; this disproportion has decreased year by year, until now the figures for adults and children are nearly equal. There was an increase of 24 in the number of new doctor members as against a gain of 12 in the previous year, attributed to sending the report for 1930 to all practitioners in the county. The amounts paid out to doctors during the year totalled £10,390, the largest totals collected for individual doctors being:—

Class of district.	*Total.*
Urban	£892
Semi-rural	£270
Rural	£503
Metropolitan area, in the administrative County of Essex	£393

The excellent work of the paid collectors of the service is demonstrated by the fact that the total arrears still average well under one-half per cent., in spite of the unemployment difficulties experienced.

and regard the work of Britain in India as coming to an end. "I do not," said the director-general, "take that view. I am convinced that, whatever constitution is established in India, the great forces to which I have referred will continue in their remorseless march, so that, even if we desire to leave India to her fate we shall be compelled to continue the work. Only the foundations of a prosperous India have been laid; the structure is far from being completed and is only now beginning to take shape. We older ones can envy the young men who are at the beginning of their career in India; they are embarking on a great adventure in which the I.M.S. will in the future play a greater part than it has ever done in the past."

THE SECRETARY OF STATE'S ASSURANCE.

Sir SAMUEL HOARE, in replying to the toast said that so far as he was concerned, and so far as the Government of which he was a member was concerned, no constitutional changes which had been made would affect the pledges which had been entered into; whatever form the constitution of India might take nothing would be done to disturb the great services which an organisation like the I.M.S. had been able to give. General Megaw's speech had, he said, started two lines of thought. The first was how hollow was the charge that we were taking more out of India than we gave; the second, how great were the benefits which medical science through the I.M.S. was conferring upon the East. Hostile critics had said that the medical services in India were being treated as a monopoly of Europeans; the I.M.S. was an outward and visible sign of the falsity of these charges. That service had been the pioneer of scientific work in the East since the days of Gabriel, Boughton, and John Howell, and their work was not confined to medical science alone. It had extended to botany, zoology, geology, veterinary science, forestry, philology, and other departments of human investigation. When the history of the British connexion in India was written it would, he was sure, prove beyond a doubt that the benefits they had been enabled to confer upon India had far outweighed any material advantages that they had gained. What a romantic history was theirs; he thought of the great work their chairman had done; he thought of the work of Sir Ronald Ross, now lying dangerously ill and whom they all sincerely hoped might soon be restored to health. Every soldier behind his mosquito net might think of how the dangers of malaria and yellow fever had been diminished, if not altogether removed, through his discoveries. Then through the work of Sir Leonard Rogers it had been possible for the first time in human history to cure leprosy in its early stages. The death-rate of cholera had been reduced from 60 to 20 per cent. Liver abscess had been wiped out of the British Army in India. Kala-azar, which between 1881 and 1900 swept up 200 miles of the Assam Valley, with a case-mortality of 96 per cent., and reappeared in 1918 after the influenza epidemic with 80,000 cases, was now in 90 per cent. of the cases cured, and might with sufficient organisation be stamped out in Bengal. What other Empire could, he asked, claim a record of this kind? The achievements of the I.M.S. were written not only in Colonel Crawford's history but in the lives of the men, women, and children which they had saved.

"To-night," Sir Samuel concluded, "I am here, as Secretary of State for India, to bear a tribute to this great record, and to ask you not to be discouraged by the uncertainty of the future. Your work, so far from being finished, is only now beginning to enter upon a new and greater advance. These scientific and biological questions are going to be of much more importance in the future than ordinary political questions. I ask you not to throw in your hand; I ask you to go on constantly in the belief that inestimable as were the benefits your service has conferred upon India in the past, it will bestow even more inestimable benefits in the future."

Sir RICHARD NEEDHAM gave the health of t
Chairman, who was, he said, returning to In
in a few days to resume his work there, and th
assured him of loyal and unswerving support in
battle against disease.

The *following is a list* of the officers present
the dinner:—

Major-Generals: Sir Havelock Charles, Bart., G.C.V.
K.C.S.I.; H. Boulton, C.B., C.B.E.; Sir Leonard Rog
K.C.S.I., C.I.E., F.R.S.; G. Tate, C.I.E.

Colonels: H. Ainsworth; J. Anderson, C.I.E.; R.
Baird; A. B. Fry, C.B., C.I.E., D.S.O.; J. Fullerg
V.H.S.; T. A. Granger, C.M.G.; C. R. M. Green;
Mackie, C.S.I., O.B.E.; Sir Richard Needham, C.I
D.S.O.; W. H. Leonard, K.H.P.; E. L. Perry, D.S.
J. J. Pratt; J. Norman Walker.

Lieut.-Colonels: W. G. P. Alpin, O.B.E.; C. H. Bar
D.S.O.; G. T. Birdwood; R. H. Bott, C.I.E.; E. W
Bradfield, C.I.E., O.B.E.; C. I. Brierley, C.I.E.; H
Cook; D. G. Crawford; J. M. Crawford; J. B. Da
Hunter, O.B.E.; C. Newton-Davis, M.C.; H. R. Dut
C.I.E.; S. C. Evans; J. K. S. Fleming, C.B.E.; P.
Fleming, D.S.O.; G. F. Graham; W. G. Hamilton; W
Harnett; T. A. Hughes; E. V. Hugo, C.M.G.; M. I
Irvine; S. P. James; H. Kirkpatrick; W. B. Lane, C.I
C.B.E.; R. F. D. Macgregor, M.C.; I. M. Macrae, C.
O.B.E.; E. G. Maddock, C.I.E.; W. T. McCowen; F. C
Mell, C.I.E.; R. V. Morrison; F. O'Kinealy, C.V.O., C.I.
T. F. Owens; A. Campbell Munro; T. R. Mulron
A. S. M. Peebles; E. S. Phipson, D.S.O.; C. H. Rheinh
M.C.; H. Ross, C.I.E., O.B.E.; J. D. Sandes; H.
Shortt; G. N. C. Smith, C.M.G.; H. B. Steen; R. St
Ashton Street; W. A. Sykes, D.S.O.; C. Thoms
A. G. Tressider, C.I.E.; H. J. Walton; E. L. Ward, C.M.
A. Denham White; R. E. Wright, C.I.E.

Majors: C. H. P. Allen; R. S. Aspinall; Sir T. C
Evans, M.C.; S. N. Hayes; J. M. Hennessy; R.
J. M. Mitchell, O.B.E.; H. J. H. Symons, M.C.; U
Salamat.

Captains: M. L. Ahuja; G. R. M. Apsey; K.
Bharucha; Dev Datt; T. J. Davidson; J. E. G
K. H. A. Gross, M.C.; W. A. Khan; C. K. Lakshman
F. E. B. Manning; E. A. O'Connor; T. S. Riddle;
Rosenbloom; J. F. Sheperd; Daswant Singh; A. T
R. K. Tandon.

Officers on Probation: Capt. J. H. Crawford; C
W. Happer; Capt. J. J. Quinlan; Capt. R. A. Wes
Lieut. F. C. Jackson; Lieut. H. Hannesson; Lieut. W.
Marrow; Lieut. R. J. Reid; Lieut. M. Sendak.

ROYAL AIR FORCE

Flight Lt. (hon. Squadron Leader) T. M. Walker employed with the Regular Air Force for a further year.

VICTORIA PARK HOSPITAL.—The report for 19 of the City of London Hospital for Diseases of t Heart and Lungs, Victoria Park, records that 10 in-patients were admitted, whose average stay w 50·27 days; their weekly cost was £3 12s. 9d. £102 £36,782 the expenditure exceeded the income by and the overdraft was just under £9000. During the ye a bronchoscopic clinic was established, and 400 patien were treated "with marked success." The pathologic department is inquiring into the effects of their occupati upon employees in asbestos works, and into pulmona tuberculosis among young women in the years of adolescenc the incidence of which is disproportionately high.

rds were abolished some such sum would be ucted from the capitation fee. The records can a very useful defence against charges by a dis-ntled patient, and do if properly kept contain portant useful information. Is it not the system ployed in the practice of keeping records that is fault? It is quite simple to use the medical record d as one of a visiting card index. Taken out in uitable wallet, with other cards, private and panel, which make up the visiting list of the day, entries are made on it at the time, and when the particular illness is sufficiently better for consultation to be restarted, the record card is removed from the daily visiting index and replaced in the consultation index. Of this it is convenient to keep two going: one, a small one, of patients who frequently attend the surgery; the other, the main index of panel patients. Records kept in this way cause little worry.

CORRESPONDENCE

HOSPHATASE AND HYPERVITAMINOSIS

To the Editor of THE LANCET

SIR,—In your issue of May 14th, in a very sane and id article on the Mode of Action of Vitamin D, . L. J. Harris makes the point that the tissues tside the bone) that become most extensively lcified in irradiated ergosterol poisoning are those ich are *richest in phosphatase.* He instances the dney and aorta as being exceptionally well provided th this enzyme. I would not comment on this atement except that some stress is laid on it (p. 1032); is again set forth in the summary, and it may rhaps pass into acceptance if it is not challenged.

In the soft tissues of the adult mammalian body, at most richly endowed with phosphatase is, in fact, ither the kidney nor the aorta but the mucosa of the nall intestine, then follows the kidney, whilst the art musculature and the aorta are almost com-letely lacking in this enzyme.[1] I do not think there any doubt about the almost complete absence of e "bone" enzyme from the aorta and arteries nerally; in between 20 and 30 samples of such sues, calcified and uncalcified, examined in this boratory it has not been possible to find more than ery minute quantities of this enzyme. Calcification the soft tissues following the administration of cess of irradiated ergosterol, which is greatest in the erial walls, rather less in the kidney, and almost in the small intestine, is thus exactly the reverse what would be expected from the phosphatase nt of these tissues.

Furthermore, arterial calcification arising in patho-ical conditions other than "hypervitaminosis D" not seem to be explicable on the basis of the hosphatase content of the calcifying tissue.

I am, Sir, yours faithfully,
H. D. KAY.

University of Toronto, Department of Biochemistry,
June 2nd, 1932

To the Editor of THE LANCET

SIR,—Prof. Kay has kindly permitted me to see advance the above letter. May I point out that exaggerates my actual conclusions in making me y that the sites which become most extensively alcified are those which are *richest* in phosphatase. drew no such strictly quantitative deductions. The information which Prof. Robison communicated o me could perhaps have been put most accurately the form that, in the case of the rat, the kidneys and the intestinal mucosa are "exceptionally rich" phosphatase, while amongst certain other tissues the aorta may contain very significant amounts. well recognised that the presence of phosphatase not likely to be the *sole* factor governing the extent f calcification, as I indicated in the original paper,[2] on which THE LANCET summary was based. I do maintain, however, that the phosphatase factor is bound to be of great importance. In the case of the kidney it will be noted that there is a correlation between calcification and phosphatase activity; as to the aorta we see that the question of its phosphatase activity is now under discussion; while it must be pointed out that the small intestine does in fact definitely show a well-marked tendency to calcification in hypervitaminosis.

It should have been made clear that the mention in my article in THE LANCET of calcification in vitro with hypervitaminosis serum carried out in collaboration with Prof. Robison related only to a preliminary experiment and that further investigations are still in progress. The interpretation was, of course, entirely my own. But it seems certain that the increased Ca × P level in the blood in hypervitaminosis is bound to favour increased calcification.

I am, Sir, yours faithfully,
LESLIE J. HARRIS.

Dunn Nutritional Laboratory, Cambridge,
June 15th, 1932.

To the Editor of THE LANCET

SIR,—Dr. Harris has referred to certain results recently obtained in my laboratory; I should be glad if you would allow me to explain these results a little more fully.

In collaboration with Miss L. M. B. Patterson and Dr. M. G. Macfarlane I have reinvestigated the relative phosphatase content of various animal tissues, employing a modified technique which, I consider, gives a more just estimate of the enzyme present. The results have confirmed the previous conclusions[1] as to the very high activity of bone, intestinal mucosa and kidney, the low activity of liver, pancreas, and muscle, and the almost complete absence of the enzyme from non-ossifying costal cartilage. In the rat certain other tissues, especially the aorta, heart muscle, lung, and thyroid have been found to contain phosphatase in significant amounts which may even exceed one-third of that in bone or kidney. Our results for other animals are not yet complete but indicate that in the rabbit and guinea-pig some of these tissues, including the aorta, may possess very much less phosphatase than those of the rat.

We have been interested to discover whether any correlation exists between the phosphatase activity of these soft tissues and their propensity to undergo calcification in pathological conditions, and hope to discuss this question very shortly. There is ample evidence that other factors besides phosphatase must be concerned in calcification, whether normal or abnormal, so that direct proportionality between phosphatase content and degree of calcification need not be expected.

Dr. Harris also referred to an experiment on especially in the districts of Chadwell Heath, Dagenham, Becontree, and Harwich. The last-named indeed depends almost entirely on its docks, where the tariffs on imported goods have already resulted in the discharge of over 200 men.

Difficulties of Insured Persons other than Certification

At a conference of doctors, chemists, and representatives of approved societies, held at Brighton on *June* 1st, Mr. R. A. Goddard (*on behalf of the* M.U.O.O.F.) asked for consideration of the difficulties of the person insured under the N.H.I. Acts, other than in relation to certification or treatment. Doctors, he said, did not always give full account for the mentality of the average insured person. He was generally a man of small education, conscious of his own inferiority. He was not always able to articulate properly what he wanted, and when he met a man of superior qualifications it was difficult for him not to adopt an aggressive resentment. When a patient went on the funds he usually gave up a low wage for a still lower sickness benefit, and he would like the doctor to have more tolerance with him. It had been said that there was an enormous amount of malingering. He agreed that there was some, and it was difficult for the doctor at times to discover what was genuine. When in doubt doctors should call in the R.M.O. Societies were objecting to unduly prolonged claims on the part of their members; they had to bear in mind that they were the trustees of funds for the benefit of those who were genuinely *ill* and entitled. He had, he said, heard of cases where doctors had not responded to calls for domiciliary visits when they ought to have done so, and cases in which the doctor had seen a patient at his surgery and ordered him to bed, and had not followed that up by paying a visit for several days. There were also cases of doctors—he was not suggesting it was general—charging fees and neglecting to follow the prescribed procedure for issuing receipts for fees, or charging for what was described (possibly rightly) as being outside the scope of a general practitioner's duty, but without informing the patient beforehand that he was going to be so charged. There was, he said, a very strong feeling that panel patients were not treated in the same way as ordinary private patients. Complaints had been made of the waiting-rooms and surgeries for panel patients being different from those used by other patients. In a few instances the doctor did not treat the insured person in the same way as he treated a private patient. He did not wish to infer *that there were numerous instances, but* a few did exist, and should be remedied. He would like to have an organisation of doctors, approved societies, and insured persons to discuss all these difficulties and see whether a solution could be found.

Dr. R. G. Chase, in reply, said he did not think any doctor present would defend discourtesy to a panel patient or omission to pay domiciliary visits when required. It was for the doctor to decide whether a visit was necessary, and he should not wait for a message from the patient. Neither would he defend doctors who kept separate waiting-rooms or separate surgeries. But with regard to what had been said as to the inferiority complex of the panel patient, he thought that explained a lot. He had been on the medical service subcommittee for London for some years, and almost all the complaints they had to deal with could be put down, indirectly if not directly, to an inferiority complex. In London, 61 per cent. of the cases (and they heard some 70 a year) were complaints against doctors for failure to provide treatment, or for neglect during treatment, or for unsatisfac conduct of the case—all of which came under complex. In fairness to the London doctors he w add that 46 per cent. of the complaints were not stantiated. What, he asked, was the cure for complex? In the first place, he thought the condit of contribution under the Act should be more explained to the insured person. He had made rule to ask insured persons who had lodged a compl whether they ever read their medical card; the g majority said they had not. That was one of difficulties of the panel patient; he did not know rules. Reference to regional medical officers w serious cause of complaint amongst the patients. was a common thing for a patient to come befo R.M.O. and refuse to be examined, saying that he perfectly satisfied with his own doctor. The R.M had then to explain that the society had a right u the rules to a second medical opinion, and tha would try to be fair. Even then, a numbe patients still complained, regarding it as a sligh their doctor, or on themselves. Societies, when sen references to the R.M.O., might well consider what patient himself thought of it. Except in a Gov ment service, he could not conceive the interposi of a second doctor between a patient and his practitioner without causing a lot of trouble. betterment of conditions of reception-rooms he not think important. An insurance practitioner in open competition with his neighbours; it was business to allow patients to sit in bad conditions, a doctor who did that would soon find that patients left him. In the matter of charging fee the cases which came before the subcommittee, 19 cent. had been complaints of this kind. In gen they were due to the insured person not kno the rules; if, for instance, a patient went to a do being on the panel of another doctor within two m it was perfectly legitimate for that doctor to ch him. Finally, he dealt with a complaint not menti by Mr. Goddard. In London there was qui common understanding amongst pregnant wo that they were entitled to at least four weeks' sick before the confinement. When about eight mon pregnant they came up saying the agent had them that they were entitled to four weeks' sick and they wanted a certificate. Possibly they doing ordinary housework, and quite capabl doing it. He wished societies would get a more c petent type of person for sick visitation. Any acting as R.M.O. must have had people sent up to whose breathing could be heard in the next ro people with splints right up to *the hip on both* walking on two crutches—and asked to certify whe these people were fit for work.

Medical Records

Medical Practitioner, N.W.1, writes:—" remarks on medical records in your issue of June (p. 1274) call for some comment. In a busy Lon practice it is almost an impossibility to enter up e time one sees a patient. In the country w patients are often seen at branch surgeries *in* outl villages, and records are usually kept at the cen surgery, it is an impossibility. Clinically, of what is it to enter up a simple cold or muscular rheumatis For his own reference and convenience the do may enter up the salient points of an important c but to be forced to enter each and every occasio a burden and worry." Doctors are however pai it is believed something approaching *2s. 6d.* per hea to keep these records, and it is almost certain tha n admission the lesion which was situated in palm of the left hand just proximal to the base the first finger was scabbed over and almost The attack was not a severe one, the general occurring only two or three times daily, the rigidity of the affected hand and arm of the jaw was more continuous. Spasms and rigidity ceased on Dec. 17th, 13 days from the of symptoms, and 21 days from the accident. overy was uninterrupted except by the occurrence uppuration at the site of the lesion which necessi- d opening and drainage. Until then no local tment had been applied. He received in all 000 English units of antitoxin, 30.000 intra- cally, 15,000 intravenously, and 30,000 intra- cularly. These were all administered within the six days after admission.

he points of interest apart from the cause were : Onset within eight days after the injury, with a tively mild attack. (2) Vigorous antitoxin treat- nt. (3) No interference with the initial lesion il it suppurated 12 days after the tetanus had sed.

I am, Sir, yours faithfully,

FREDERICK LANGMEAD.

t. Mary's Hospital, W., June 20th, 1932.

ANTIBODIES IN YELLOW FEVER

To the Editor of THE LANCET

SIR,—In your issue of June 11th your reviewer of monograph on "Filterable Virus Diseases in n" declares me guilty of a contradiction when tate (*a*) that the serum of yellow fever convalescents capable of protecting against an injection of ective blood, and immediately afterwards (*b*) that ither immune bodies nor viricidal properties have en demonstrated in the serum of convalescents.

I cannot agree that there is any contradiction. hen a serum confers passive immunity, it is legiti- ate to infer that "protective substances" are esent, but it is not equally legitimate to infer the chanism of the protection without further evidence. cannot, for example, be directly inferred that the is viricidal. If an infective dose is given sequent to the protective serum, then the resulting may be equally well explained by the iricidal properties of the tissues (no doubt in some modified by the passively protecting serum) by such properties of the protective serum itself. he only *evidence* that the serum is viricidal would an experiment in which the protective serum first mixed with the infective dose. Even then e absence of symptoms after an injection of the ixture need not be explained by the viricidal roperties of the serum, for if interaction of the tissues nd the protective serum were essential for the laboration of the viricidal bodies, then obviously e virus would remain unaffected after mixing ith the serum, and only after injection of the mixture ould the viricidal bodies appear. Hence the mixture ould have to be freed from serum by centrifugalising nd washing the bottom layer with saline; the bsence of symptoms after inoculation of the washed irus can then be taken as evidence of viricidal bodies the protective serum. From the very nature of e filterable virus, the presence of viricidal bodies ust be more difficult and more exacting than the emonstration of bactericidal bodies. In the same ay the presence of immune body—i.e., amboceptor— not to be directly inferred from the fact of passive immunity, however reasonable it may be to anticipate its presence; the usual evidence must first be sought of the ability of the immune serum to deviate compliment in the presence of antigen.

Hence in making the statements which your reviewer criticises I have not been guilty of a contradiction, although indeed I may have been guilty of overlooking the experimental evidence I sought of the existence of viricidal bodies or of amboceptor. Since the publication of my book, although only a few months ago, yellow fever research has made considerable progress, including proof of the presence of complement-fixing bodies[1] in convalescent serum, and successful cultivation of the virus in tissue culture medium.[2]

I am, Sir, yours faithfully,

J. FINE.

University of Edinburgh, Usher Institute of
Public Health, June 13th, 1932.

*_** All the available evidence, both in the case of the cultivable bacteria as well as the filtrable viruses, goes to show that the power of a serum to confer passive immunity is a function of its antibody content. In his article on yellow fever in "A System of Bacteriology" (vol. vii.), Prof. E. Hindle states (p. 458), "Experiments with the serum of both man and monkeys after recovery, show that immune bodies are present in considerable strength." The presence of neutralising antibodies in the serum of yellow fever convalescents was demonstrated by Stokes, Bauer, and Hudson in 1928 (*Amer. Jour. Trop. Med.*, viii., 103), and again by Hindle in 1929 (*E. Trans. Roy. Soc. Trop. Med. and Hyg.*, xxii., 405), and specific complement fixation was obtained by Monteiro and Travassos in 1930 (*Compt. Rend. Soc. Biol.*, civ., 290), and by N. P. Hudson in 1931 (*Arch. Path.*, xi., 326). Other work bearing on this point could be cited, but these references are picked out to show that considerable evidence exists of the presence of specific antibodies in the serum of yellow fever convalescents.—ED. L.

ADSORPTION OF IODINE BY ACTIVATED CARBON

To the Editor of THE LANCET

SIR,—In his paper in your issue of April 2nd (p. 724) Mr. B. A. Adams states that he employed the sodium nitrite method of Martindale and Westcott for the determination of iodine in water. May I point out that according to Dr. Martindale ("Extra Pharmacopœia," 1929, ii., 425) the limit of delicacy of this method is about 18 gamma (gamma = 0·001 mg.) of iodine—i.e., approximately ¾ gamma per litre on a 25-litre quantity of water. From my own experience this is, if anything, a somewhat liberal estimate of the delicacy of the test. Since Mr. Adams worked on only 2 litres of water he would have been unable to detect less than 9 gamma of iodine per litre—i.e., 45 per cent. of the total 20 gamma per litre which he added to the water before carbon treatment. Under these circumstances it can hardly be taken as conclusive that because no iodine was detected it had been adsorbed by the activated carbon "invariably and completely." In order to justify such an assumption it would be necessary to examine far larger quantities of water than 2 litres, preferably with control tests on the water before carbon treatment.

I am, Sir, yours faithfully,

Maldon, Essex, June 1st, 1932. G. U. HOUGHTON.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

LEVERHULME RESEARCH SCHOLARSHIPS

To the Editor of THE LANCET

SIR,—The reference which you make in your issue of June 11th (p. 1266) to the Leverhulme Research Scholarships at the Royal College of Physicians would, I am afraid, lead your readers to assume that these scholarships were being given by myself personally. I think it only right to point out that they have been given by the trustees (of whom I am one) appointed to administer a special trust fund under the will of my father. The scholarships are, therefore, virtually a gift from my late father, and it is for this reason that the Royal College of Physicians proposes to call them the "Leverhulme Research Scholarships."

I am, Sir, yours faithfully,

June 18th, 1932. LEVERHULME.

APPENDICITIS

To the Editor of THE LANCET

SIR,—If Mr. E. R. Flint had read my letter more carefully he would hardly have drawn such erroneous conclusions as to my practice. To suggest that I wait "until the appendix has perforated in order to get a clear indication for operation" is an inference which cannot be drawn from my letter. What I did say was that if operation be delayed for a few hours, the symptoms *frequently* subside so *that operation* can be deferred, sometimes avoided. If the symptoms do not subside, obviously the morbid process is progressive and operation should be performed *before* perforation occurs. The indication for operation is not perforation, but non-subsidence or exacerbation of the symptoms which suggest that perforation may occur. Neither did I say that even when this catastrophe has occurred I "spend several hours in giving saline, &c., *with the hope that the symptoms will subside*" (the italics are mine). On the contrary, I wrote "Perforation . . . is obviously an indication for operation." I can assure Mr. Flint that the catastrophes he fears do not occur when the expectant treatment is carried out with the exercise of common sense.

Mr. Flint says that the ideal treatment is operation within a few hours of onset. But is it ideal from the patient's point of view? This teaching premises that diagnosis is an exact science. If Mr. Flint maintains that he can make a certain diagnosis within a few hours of onset in every case of abdominal pain, then there would be some justification for this teaching, otherwise it is certainly not ideal from the patient's point of view. A patient would scarcely regard operation as the ideal treatment for intestinal colic, and yet in the initial stages of an attack of abdominal pain it is not always possible to be certain that the fons et origo mali is the appendix. What if the patient on whom an unnecessary operation is per-
formed dies? Such a happening is not unk
A few years ago there was such a tragedy wi
short distance of the room in which I write.

The argument that it is better occasionally to re
a healthy appendix than to lose one patient'
through taking the risks of delay is a plausibl
fallacious one, for I maintain that the expe
treatment is not taking risks but diminishing
provided that the patient is kept at absolute res
that no purgatives are administered. The risk
injudicious use of purgatives is one that cann
emphasised too often. Perforation without lo
tion is almost always the result of disregard of
precautions.

Surgery is an art, not a science; and being an

ly, to dominate more completely the environ- . The other two factors are the promotion e fore limb to a delicate explorer of space in fold directions, and the organisation of mimetic ments to express thoughts by sounds.

baby announces its presence in a way that s no doubt as to the power of its laryngeal ulature. Yet later on it has to learn how best xpress thoughts by sounds. Is that done by s calculated to increase the power of his speaking les? Later on the child arrives at the school nd is going to learn how to use his fore limb delicate explorer of space in a very special way ., to form letters and words in writing. Is this se its writing muscles are lacking in power? e not have to curb in our babies the utterances ryngeal power, and must we not protect living other valuables against the manifestations of al and digital muscle-power of our young ? Likewise my astheno-vergence patients will squint internally to 60°–75°, while they only produce *involuntary* convergence to, say, f deviation. Education enables the centres for movements and for speech in the neo-pallium ain better control over the motor-coördinations ding over the powerful musculature of the heral organs concerned. Likewise, kinetic treat- enables the centres for convergence in the neo- um to gain a surer control over the midbrain es for ocular movements in the interest of veal single vision.

have chosen "amblyopia" and not "fatigue" as erm for the partial loss of sight under considera- , because in all my patients treated for eyestrain on unt of astheno-vergence I never saw an instance of nic fatigue (mental or other), except in the only neurotics I tried to treat kinetically. If I I would not have given them a strenuous kinetic ment, but would rather have prescribed them tal and visual rest. My astheno-vergence nts were without muscular eye defects and inly not "run down in health." The partial of sight was not attributable to any other cause to chronic inability of long standing to bring two foveal images to cover one another com- ly, accurately, and at any moment required. adults treated by me for astheno-vergence almost without exception vigorous, healthy, , hard-working men and women; the children ted were, apart from astheno-vergence, normal. ade the mistake—unavoidable at the time—of ting also three patients of neurotic disposition, these treatments were notable failures. These ents may have suffered from mental fatigue but, ting that they did, I cannot see why the term nblyopia" should not be applied to such cases. use the word fatigue in this connexion would be uly stretching its usual meaning. I could, aps, admit that fatigue is a link in the chain ausality of the partial loss of sight in this sense; the chronic inability to bring the two visual to meet accurately on the object of vision lays rain on the visual centres, a strain which leads to a ain amount of exhaustion or fatigue of the motor of these centres, and that in the long run a giving , a kind of neutralisation of vision of on or both manifests itself in amblyopia. But the amblyopia observed fact, the mental fatigue only a hypothesis xplain the fact.—I am, Sir, yours faithfully,

hannesburg, S. Africa, May 4th. N. A. STUTTERHEIM.

** We spoke of the claim to cure amblyopia y means of prisms calculated to increase the power of the converging *muscles*," whereas in the cases referred to it is not the muscles that are defective but the nervous mechanism which governs their action in converging the two eyes on any given point, and we accept Dr. Stutterheim's correction without reserve. It is not hard to understand that by his exercises he succeeds in so toning up the reflex nervous mechanism that the range through which "involuntary convergence" is effective in overcoming prisms base out, with the eyes fixed on a distant object, can be greatly increased in most healthy subjects. It is far more difficult to accept his claim that visual acuity, both binocular and monocular, can be definitely increased by these methods. When this happens the explanation may, as we suggested, be the overcoming of fatigue affecting, on the one hand, the nervous mechanism through which convergence of the two eyes to any given point is effected, and, on the other hand, the nervous mechanism by which the retinal images of one or both eyes are interpreted. This explanation may not be correct, but the claim to cure "amblyopia" by Dr. Stutterheim's procedure is so startling that one seeks for some explanation to make it seem possible.—ED. L.

TRAINING IN MASSAGE AND MEDICAL GYMNASTICS

To the Editor of THE LANCET

SIR,—It has come to the knowledge of the Chartered Society of Massage and Medical Gymnastics that there are a number of organisations in London and in provincial towns which profess to give a training in massage and medical gymnastics by correspondence, and which issue certificates and diplomas. These subjects necessitate a considerable knowledge of anatomy, physiology, pathology, medicine, and surgery as well as technical ability and clinical experience. This knowledge and experience can only be obtained by personal teaching and by the actual treatment of patients. It is to be hoped that members of the medical profession will inquire critically into the qualification and experience of masseurs and masseuses who offer to assist them in treating their patients, and that they will not be deceived by diplomas granted after a correspondence course or some other totally inadequate system of training.

I am, Sir, yours faithfully,

R. C. ELMSLIE.

Portland-place, W., June 9th, 1932.

BORACIC POWDER AND VACCINATION

To the Editor of THE LANCET

SIR,—In your issue of June 11th (p. 1288) a question was asked in the House of Commons regarding the use of boracic lint in vaccination in the Army. The answer was given that it was to be abandoned on the score of economy, but that boracic powder and ordinary lint would be issued instead. If this is correct it is a pity that the mistaken use of boracic in dressing a vaccinated arm should be continued. It is directly responsible for the irritation so frequently seen. Since substituting plain sterile gauze I have not seen one single case of irritation, whereas previously it was the rule rather than the exception.

I am, Sir, yours faithfully,

June 10th, 1932. Late R.A.M.C., T.

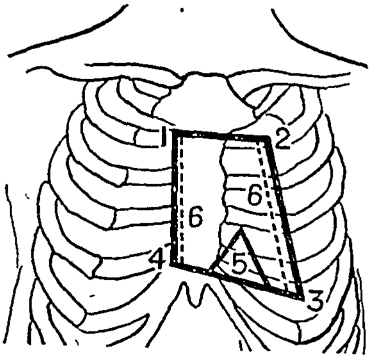
AFFECTIONS OF THE GALL-BLADDER AND CARDIAC PAIN

To the Editor of THE LANCET

SIR,—The communication by Dr. Charles H. Miller on this subject to THE LANCET of April 9th leaves little room for discussion, because of its informatory value, but I should much like to suggest that the term "cardiac pain" is a positive assertion relating to a particular organ. For the last 25 years I have in my notes used the words "cardiac area pain," a term which expresses a symptom, and that a diagnosis has to be made.

In general practice, where scientific niceties sometimes have to go by default, it is more necessary to have a definite clinical basis to work upon. A cardiograph is not easily read. Blood pressure is a will-o'-the-wisp, and only of value after many records have been taken and with full consideration of the circumstances occurring before making them. The size and position of the heart, in spite of a definite departure from anatomical correctness, may be the normal condition of the individual.

To assist in drawing the right lessons from "heart area pain" and accompanying skin tenderness (if any), I make a surface plan, showing six places or points in the cardiac area, the inner end of the right costal cartilages and the outer end of the left costal cartilages forming the lateral boundaries. To each point I attach a mental signpost, on which are recorded various common diseases. The diagram is a quadrilateral with four anatomical corners (points) and one triangular space in the middle third of the base line, the apex being above the line. The points are: (1) the junction of the right second costal cartilage and the sternum; (2) at the junction of the left second costal cartilage with the rib; (3) at the centre of the left fifth intercostal space in the line of juncture of the costal cartilages and ribs; (4) at the junction of the right sixth costal cartilage and the sternum. These four points are joined up with a skin pencil. (5) The middle third of the line 3—4 corresponds to the base of an equilateral triangle; (6) represents all the costal cartilages in the area.



Against these figures I visualise the following diseases, and proceed to verify a distal heart hint into possibly a local truth: (1) and (2) Aortic, heart, and thymus disease. (3) Mobile kidney, liver, spleen, diseases of rectum and anus with occasional shooting pain along line 2 to 3. Diseases of the gall-bladder also show hyperæsthesia of the *right* fifth or sixth intercostal nerve. (5) Stomach and duodenum affections. (6) Hyperæsthesia and pain over the costal cartilages suggest pleuritic adhesions and neurosis, such as follows an old herpes zoster. Late manifestation of diseases mentioned under above headings show one or more tender cartilages. In advanced diseases all six points may participate as reflex phenomena.

I will add three illustrative cases:—

(1) In the late spring of 1922 Sir Fredk. Treves
to see him during a visit he was paying to We
I was then in practice in Dorchester. He was co
of cardiac distress, and was very nervous about his
He referred his pain to the area I have described a
in the diagram; also there was a tender right sixt
costal nerve. I assured him he had gall-bladder
he did not agree, and was confident his heart was
In December, 1923, he died from a perforated gall-b

(2) Dr. K., aged 65, complained of cardiac area
and shortness of breath—he had a sensitive No. 3 a
tender right sixth intercostal nerve. He would no
that his gall-bladder was the cause. Nine month
at 3 A.M., I was sent for. He was suffering from
abdominal pain and retching, which he persisted in
appendicitis. His general collapse was so serious
surgical measure could be contemplated. Ten day
in consultation with the late Dr. Hyla Greves and
approval, I removed a gall-bladder containing abo
stones, ranging in size from a split pea to a small
He made a good recovery.

(3) Dr. C., aged 56, was cranking up his car a
seized with acute upper segment abdominal pain; o
later he motored home five miles. I saw him in cons
with his partner, and found a very sensitive fifth a
board-like abdominal muscles; he declared he h
pain." His contracted pupils led me to ask him how
morphia he had taken; he owned up to half a
Within three hours I opened his abdomen, and f
rupture of his duodenum. He recovered.

My diagram I have found more useful in early
when the reflex phenomenon of heart area p
always greater from remote disease than wh
heart is the primary cause.

AMBLYOPIA OR FATIGUE?

To the Editor of THE LANCET

SIR,—The annotation with this heading in
issue of April 9th (p. 789) misrepresents the poi
view taken in my paper on Amblyopia in the
issue (p. 774), where I am said to claim "to
cured many cases of amblyopia associated
weak converging power by treatment by mea
prisms calculated to increase the power of the
verging muscles." Herein lies the misconce
of my hypothesis, because astheno-vergence is
due to weakness of the converging muscles but t
weakness of response to its natural stimulus
reflex controlled by a centre situated in the b
In the paper reviewed and in my previous publica
there is not a single indication that I have
given treatment calculated to increase the
of the converging muscles. I have never met w
case of astheno-vergence (weakness of involu
convergence) due to weakness of the ocular mu
On the contrary I have often drawn attention t
fact that weakness of the eye musculature is
of the question in the diagnosis of astheno-verg
Your annotation says:

> "We would suggest to Dr. Stutterheim that the
> amblyopia is hardly a suitable one for a psychical con
> that affects both eyes, and that any measures that pr
> an amelioration of this condition are effective not so
> through the muscles as the mind."

But I have *taken great* care to point *out that*
vergence (the visual reflex) is not a muscular func
of "low level" in the hierarchies of the brain or m
as for instance adduction, which can be prod
probably even by the lowest mammals, but a func
of the highest mammalian minds—a kinetic functi
very high rank—one of the three chief factors
use the words of Sherrington, of man's outstrip
other competitors in progress towards that
which seems the universal goal of animal behavi
